33. Mangrove Honeyeater

Lichenostomus fasciolaris

French: Méliphage des mangroves **German:** Mangrovehonigfresser **Spanish:** Mielerro de Manglar
Other common names: Fasciated/Island/Scaly-throated Honeyeater

Taxonomy. *Ptilotis fasciolaris* Gould, 1854, Moreton Bay, Queensland, Australia. Forms a superspecies with *L. virescens* and *L. versicolor*. Formerly considered conspecific with latter, with which it apparently hybridizes to limited extent at N end of range (near Townsville). Monotypic.

Distribution. Coastal E Australia from NE Queensland (Ross R, near Townsville) S, including islands from Whitsunday Group S to Moreton Bay, to NE New South Wales (Tweed R–Tweed Heads, and disjunctly farther S near Broken Head, Clarence R and mouth of Macleay R, and once at Wauchope, on Hastings R).

Descriptive notes. c. 19.5 cm; male 23.9–33.1 g, female 22–30 g. Plumage is olive-brown above, grading to greyish-brown on rump and uppertail-coverts, with fine dark streaking on top of head and hindneck, diffuse brown mottling on anterior upperbody, and olive mottling on uppertail-coverts; broad black mask extending well down side of neck (and including upper ear-coverts, which can appear paler than rest of mask), bordered below by yellow stripe (combination of pale yellow to off-white gape, narrow yellow moustachial stripe, and yellow lower ear-coverts) that ends in small white tuft (white rear lower ear-coverts), and

meets large greyish-white patch on lower side of neck; tail and upperwing olive-brown, dull olive-green outer edges on rectrices and remiges (forming greenish sides of tail, greenish panel on folded wing); chin and throat finely barred dark grey-brown and dull yellow; upper breast dark greyish, forming breastband, rest of underbody off-white with heavy greyish-brown streaks (sparsely on belly), undertail grey-brown, underwing cream to buff-pink with grey-brown trailing edge and tip; iris blue-grey; bill black; legs dark grey or bluish-grey. Sexes alike in plumage, male slightly larger than female. Juvenile is very similar to adult but plainer and duller, with no streaking or mottling on top of head and anterior upperbody, slightly browner rump and uppertail-coverts, pale yellow chin and throat slightly mottled (not barred) brown, paler breastband, weaker streaking below. **Voice.** Song loud, melodious and ringing, but varying, e.g. “whit-u-we-u”. Also scolding chatter.

Habitat. Mainly mangrove forests and woodlands fringing coasts, bays, estuaries and islands; less often in coastal shrubland, woodland or scrub (e.g. of *Eucalyptus*, *Banksia*, *Melaleuca* or combinations of these) near mangroves; regular visitor to parks and gardens in some towns near mangroves.

Food and Feeding. Nectar and invertebrates, possibly fruit. Invertebrates include insects, marine snails (Gastropoda) and crabs (Decapoda). Forages mainly in mangroves (e.g. *Aegiceras*, *Rhizophora*), among outer foliage, at flowers and, at low tide, over lower trunks, roots and pneumatophores; visits flowering trees and shrubs (e.g. *Banksia*, *Castanospermum*, *Erythrina*) in adjacent habitats. Gleans invertebrates, and once seen while trying to extract a leaf-curling spider from its leaf. Active, noisy and pugnacious. Usually singly or in small loose groups.

Breeding. Aug–Dec (peak Sept) and in N of range also Apr–May. Nest cup-shaped, of dried grasses and seagrass or plant fibre bound with spider web and matted egg sacs, lined with fine rootlets or fine grass, hair and plant down, for two nests external diameter 8.9–9.5 cm, depth 5.7–7.6 cm, internal diameter 6.4–7.6 cm, depth 3.8–5.1 cm, usually suspended by rim, occasionally supported, 0.5–2.7 m above ground (one was 1.2 m above ground and 0.75 m above high-water mark), almost always in small, dense mangrove but once in *Acacia* shrub, and reported in mistletoe (Loranthaceae). Clutch 2 eggs (single-egg clutches perhaps incomplete); no data on incubation and nestling periods; both adults feed nestlings and fledglings. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*), and perhaps Horsfield’s Bronze-cuckoo (*Chrysococcyx basalis*).

Movements. Resident; some local movements to exploit flowering vegetation. In Moreton Bay, in SE Queensland, numbers increase May–Jun and decline Jul–Dec, possibly result of local seasonal movements. Vagrant on One Tree I, in Capricorn Group (S Great Barrier Reef).

Status and Conservation. Not globally threatened. Restricted-range species: present in East Australian Mangroves Secondary Area. Fairly common locally; rare in S of range. No estimates of abundance levels. Possibly adversely affected by coastal development in some areas. Range thought to have expanded S over last 50 years, with first records at Yamba (where now resident) in 1947, and some records farther S (e.g. near mouth of Macleay R in 1958, and slightly farther S in 1961).

34. White-gaped Honeyeater

Lichenostomus unicolor

French: Méliphage unicolore **German:** Wulsthonigfresser **Spanish:** Mielerro Unicolor
Other common names: White gaped/Erect-tailed/River/Uniform-coloured Honeyeater

On following pages: 35. Yellow Honeyeater (*Lichenostomus flavus*); 36. White-eared Honeyeater (*Lichenostomus leucotis*); 37. Yellow-throated Honeyeater (*Lichenostomus flavicollis*); 38. Yellow-tufted Honeyeater (*Lichenostomus melanops*); 39. Purple-gaped Honeyeater (*Lichenostomus cratitius*); 40. Grey-headed Honeyeater (*Lichenostomus keartlandi*); 41. Yellow-plumed Honeyeater (*Lichenostomus ornatus*); 42. Grey-fronted Honeyeater (*Lichenostomus plumulus*); 43. Fuscous Honeyeater (*Lichenostomus fuscus*); 44. Yellow-tinted Honeyeater (*Lichenostomus flavescens*); 45. White-plumed Honeyeater (*Lichenostomus penicillatus*); 46. White-fronted Honeyeater (*Purnella albifrons*).

Taxonomy. *Ptilotis unicolor* Gould, 1843, Port Essington, Northern Territory, Australia.

Thought to form a species group with *L. flavus*. Monotypic.

Distribution. N Australia from Melville I and N Western Australia (Kimberley Division and off-shore islands) E throughout Top End of Northern Territory (S to upper Victoria R in SW and to Barkly Tableland in SE), and on Groote Eylandt, to N Queensland (S to near Proserpine; occasional records farther S, e.g. Mackay, and on Atherton Tableland).

Descriptive notes. Male 19–22 cm, 27.8–40.4 g; female 17–20 cm, 25–33 g. Plumage is plain dark olive-brown to greyish-olive above, and slightly paler and greyer below, slightly paler on vent and with faint pale yellow tinge on centre of belly; diffuse dusky lores, white to cream gape bulging upwards in semi-circular patch; tail feathers and secondaries have faint greenish wash on outer edges, primaries have fine off-white outer edges; undertail olive-grey, underwing greyish-white and merging into dusky on trailing edge and tip; iris brown or grey-brown, sometimes olive-grey or blue-grey; bill black; legs dark grey to black, soles paler. Sexes alike

in plumage, male slightly larger than female. Juvenile is very similar to adult and some probably inseparable in field, but initially distinguished by combination of softer plumage of upperbody, faint brown tinge on hindneck, upper mantle and rump, slightly stronger yellow wash on centre of belly, and (at least sometimes) brighter yellow gape. **VOICE.** Song loud and ringing or fluting, three similar phrases separated by interval of c. 0.5 seconds, e.g. “whit-o-wee” or “whit whit, awhit-whit, awhit-whit”; usually as duet whenever pair-members meet and to advertise territory, male initiating duet and female joining in after a pause (second and third phrases completely synchronized); can start song before alighting from flight, and male may respond instantly with loud song to unusual sounds, to entry of rival into territory, or to approach of potential predator. Apparent contact call, given frequently, “chiew” or “chop”, uttered at intervals of many seconds to minutes, also as nearly monosyllabic clicking “tyiet”; other calls include short, harsh repeated “chirrup” or “chirp” or rapid “chp-chp-chp-chp-chp-chp”, seldom heard and thought to be a contact call, also a soft warble by brooding bird on approach of mate, also loud chattering. Snaps bill during agonistic interactions.

Habitat. Mainly riparian forests and woodlands, frequently riverine or swamp associations dominated by paperbarks, e.g. weeping paperbark (*Melaleuca leucadendra*), or, less often, *Lophostemon*, or mixed assemblages of *Melaleuca*, *Lophostemon*, *Eucalyptus*, casuarina or *Erythrina*, and usually with dense thickets of screw-palms (*Pandanus*) and *Acacia* in understorey, or in mixed stands of *Eucalyptus* and *Pandanus*. Commonly also in monsoon rainforests. Ranges into open eucalypt woodland or savanna adjoining riverine forest, usually with grassy understorey and scattered shrubs or shrubby understorey; and occurs in ecotone between monsoon forest and open forest of acacias and eucalypts. Sometimes in mangroves, in *Acacia* forest or scrub, in spinifex (*Triodia*) grassland with scattered shrubs on sandstone plateaux, and in wet mosaic grassland and sedgeland. Also in gardens and parks in towns and around human habitation.

Food and Feeding. Diet includes nectar, fruit, seeds and invertebrates (mainly insects, also spiders). Usually forages in dense vegetation, from canopy to near ground; mostly on bark of trunks and branches of trees, shrubs and palms, or among green or dead foliage, but also on fruit and at flowers of trees and shrubs, and in air. Selects flowers that provide best source of nectar, which obtained by probing. Arthropods mainly gleaned from foliage (including palm fronds) and bark; captures aerial insects by sallying, less often performs sally-hovering to take prey from foliage, or flutter-chasing. Inspects spider webs; searches around buildings and even enters them. Seen to eat arils attaching seeds to seedpods of black wattle (*Acacia auriculiformis*). Usually singly, in twos (probably pairs) or threes, or in small groups of up to 6–8 individuals; sometimes feeds with other honeyeaters, or with other bird species.

Breeding. Probably throughout year, and recorded in all months except Jun near Darwin (Northern Territory); clutches Jul–Mar. Nest built by female, accompanied by male, a deep cup, usually made of bark or grass, bound with spider web or spider egg sacs, sometimes includes rootlets, grass, hair, plant fibres, twigs or casuarina needles, unlined or sparingly lined with fine grass and with plant down, nest said by some authors to be covered with shining layer of saliva (which helps to bind materials and make nest solid), external diameter 8–12.1 cm, depth 7–8.9 cm, internal diameter 5.4–8 cm, depth 3.8–6.4 cm; usually suspended from twig fork in topmost branches of live leafy tree or shrub, including mangrove and in mistletoe (*Loranthaceae*), occasionally near centre of tree, usually near water; six nests were 1.5–3.3 m (mean 2.18 m) above ground, but others reported as low as 1.2 m and as high as 12 m. Clutch usually 2 eggs; incubation by female, from second egg, period 15–16 days; chicks brooded by female, or allegedly by both parents, fed by both parents (possibly by female only for first 2 days), nestling period at one nest 13–14 days; both adults feed fledglings.

Movements. Resident. No evidence of nomadism, but possibly moves locally to exploit flowering; at Victoria River Downs, local range contracts during dry season. Occasional visitor or vagrant to sites at edge of range; unconfirmed early report from NE New South Wales.

Status and Conservation. Not globally threatened. No estimates of total population; recorded densities of up to 2 birds/ha. Formerly considered common at Mt Isa, in NW Queensland, but now recorded only N of there; formerly considered common or recorded at Ayer and Mission Beach, but no recent records. In study of effects of long-term exclusion of fire in Northern Territory forests, this species was found to be significantly more abundant in unburnt quadrats.

35. Yellow Honeyeater

Lichenostomus flavus

French: Méléphage jaune **German:** Zitronenhonigfresser **Spanish:** Mielero Amarillo
Other common names: Broadbent's Honeyeater

Taxonomy. *Ptilotis flava* Gould, 1843, Port Essington, N coast of Australia = Cape York, north-east Queensland, Australia.

Thought to form a species group with *L. unicolor*. Geographical variation possibly clinal (e.g. wing length appears to decrease clinally from S to N, but much individual variation), and differences

between races slight; races appear to be separated by high ridges of Burdekin–Lynd Divide but may come into contact along narrow lowland corridor E of Great Divide, and apparently intergrade where they abut; more material from S of range required. Two subspecies provisionally recognized.

Subspecies and Distribution.

L. f. flavus (Gould, 1843) – Cape York Peninsula and coastal and subcoastal far NE Queensland S to about Burketown (SE Gulf of Carpentaria) in W and to Burdekin–Lynd Divide in E.

L. f. addendus (Mathews, 1912) – coastal and subcoastal CE Queensland, from high country of Burdekin–Lynd Divide S to Broad Sound.

Descriptive notes. c. 18 cm; male 19–30.8 g, female 16–25.4 g. Nominata race mainly olive-yellow above and on side of head, lemon-yellow below; diffuse lemon-yellow patch behind eye (sometimes extending narrowly over eye) and lemon-yellow moustachial stripe, isolating dusky olive-yellow eyestripe, and with narrow olive-yellow submoustachial stripe and lemon-yellow chin and throat; remiges and rectrices have broad lemon-yellow outer edges (folded wing and side of tail brighter yellow than upperparts); undertail dull olive-yellow; underwing yellow with brownish-grey trailing edge and tip; iris olive-grey to dark brown; bill black,

gape black or yellow (possibly varying seasonally); legs brownish-grey at front, brownish-orange at rear. Sexes alike in plumage, male larger. Juvenile is similar to adult but duller, with less obvious facial pattern, plumage also appears softer, and gape also puffy and yellow (at least at first). Race *addendus* tends to be slightly duller olive above than nominate, and has faint greyish-olive wash on breast and flanks, faint and diffuse darker streaking on flanks. **VOICE.** Vocal, especially at roosts or when mobbing; calls in flight. Four vocalizations distinguished in one study. Song a loud, melodious whistle, heard throughout day; also in duets, male and female alternating with different segments of song. Also gives short trill that ends in sharp whistle; noisy metallic “tut-tut-tut”; and soft mellow chattering notes. Other calls (either different descriptions of above-mentioned or possibly separate vocalizations) include piercing “whee-whee”, bold loud clear whistling note, merry “whee-a, whee-a”, and loud single high-pitched whistle; also short squeaky chirrup; and peevish, scratchy “jab!” in alarm.

Habitat. Open riparian forests and woodlands, particularly around swamps and other wetlands, typically dominated by *Eucalyptus* and frequently with understorey of paperbarks (*Melaleuca*) and bottlebrushes (*Callistemon*); also riparian forests and woodlands dominated by paperbarks and *Lophostemon*, often with dense understorey of palms. Sometimes in ecotone between forest or woodland and rainforest, or at edges of rainforest patches (but not within extensive rainforest), and in mangroves. Often in agricultural land, including sugar-cane crops, and in parks and gardens in towns and cities. Mainly coastal lowlands, extending into ranges and tablelands, occasionally as high as c. 1100 m.

Food and Feeding. Diet includes nectar, fruit and small arthropods (mainly insects, some spiders). Forages mainly in trees and shrubs, among foliage, trunks and branches, at flowers, including mistletoe (*Loranthaceae*) flowers, and fruit, sometimes in air or on ground. Nectar obtained directly by probing; insects gleaned from foliage and twigs, seized in aerial sally, or caught in sally-hover in front of spider webs. Acrobatic, often hangs upside-down to reach food. At a sugar mill, seen to feed on sugar accumulated along rafters, conveyor belts and beneath storage bins, and to drink molasses from drains. Usually singly, in pairs or in small groups of 3–4 individuals; will congregate at sources of abundant food (e.g. flowering eucalypts, paperbarks or mistletoes), where can associate with other species; once seen in loose mixed-species meliphagid flock with over 75 individuals of ten species.

Breeding. Recorded in all months, clutches Aug–May and nestlings Sept–May; one pair known to have raised three broods in one year. Occasionally co-operative breeder, with helper at nest. Nest probably built only by female (offspring from previous season once seen to assist), a shallow, often lightly constructed cup of bark with some grass, less often fibrous roots or palm fibres, sometimes bound together (and to nest plant) with spider web and arthropod egg sacs, usually lined with fine grass or bark, sometimes unlined, external diameter 7.5–8.9 cm, depth 5.1–7 cm, internal diameter 5.5–7 cm, depth 3.2–5.1 cm; usually suspended from fork or thin twigs 0.7–7.8 m (mean 4.1 m) above ground, occasionally higher (to 9 m), in leafy shrub or tree, but sometimes supported, reported also in mistletoe, one attached at three points with spider web. Clutch usually 2 eggs, mean 1.92 (clutch of 4 incubated, and almost certainly laid, by two birds); incubation by female, period c. 16 days; roles of sexes in brooding not known, probably by female only, chicks fed by both parents, sometimes by helpers when present, nestling period 12–14 days; both parents feed fledglings. Nests parasitized by Brush (*Cacomantis variolosus*) and Pallid Cuckoos (*Cuculus pallidus*). From 39 eggs in 20 nests, 0.75 fledged young per nest; of 29 nests, 48.3% successfully fledged at least one young.

Movements. Resident throughout range; in study of colour-ringed population at Townsville, found to be sedentary and territorial throughout year. Claims of nomadism at some sites appear to refer to local movements to exploit flowering.

Status and Conservation. Not globally threatened. Fairly common. No estimates of total population; recorded density of 0.02 birds/ha along Lockhart R.

Bibliography. Barrett *et al.* (2003), Beruldsen (1979), Blakers *et al.* (1984), Bravery (1970), Campbell (1900), Colston (1974), Cooney *et al.* (2006), Ford (1986, 1988), Ford *et al.* (1980), Forshaw & Muller (1978), Gannon (1962), Garnett & Bredl (1985), Garnett & Cox (1983), Griffiths & Clarke (2002), Higgins (1999), Higgins *et al.* (2001), Keast (1968a, 1985a), Lavery *et al.* (1968), Marshall (1934a), McLean (1995), Nielsen (1996), North (1907), Pizzey (1980), Sage (1994), Schodde & Mason (1999), Storr (1953, 1984), Thomson (1935), Wheeler (1967b), White (1922).

36. White-eared Honeyeater

Lichenostomus leucotis

French: Méléphage leucotique **German:** Schwarzkehl-Honigfresser **Spanish:** Mielero Orejiblanco
Other common names: Australian White-eared Honeyeater; New Norcia Honeyeater (*novaenoriae*)

Taxonomy. *Turdus leucotis* Latham, 1801, Nova Hollandia = region of Port Jackson, New South Wales, Australia.

Forms a superspecies with *L. flavicollis*. Nominata race and *novaenoriae* intergrade along inner slopes of Great Divide from SE Queensland S to SE South Australia. Three subspecies recognized.

Subspecies and Distribution.

L. l. novaenoriae (Milligan, 1904) – S Western Australia (S from Kalbarri area) E to W edge of Nullarbor Plain, and across coastal and subcoastal mallee to SE South Australia (S from S Flinders Ranges), and from E Queensland (S from Burra Range, E of Hughenden) S through E Murray–Darling Basin and W watershed of Great Divide to SW & SE New South Wales and adjacent Victoria.

L. l. leucotis (Latham, 1801) – SE Queensland (about Bunya Mts) S, on and E of Great Divide, to Victoria and SE South Australia.

L. l. thomasi (Mathews, 1912) – Kangaroo I, in SE South Australia.

Descriptive notes. 16.5–21.5 cm; male 18–35 g and female 18–30 g (nominate), male 15–28 g and female 15–21 g (*novaeboracae*). Nominate race is bright olive-green above and paler yellow-olive below, with grey top of head and hindneck finely streaked black (except on forehead), and black side of head and neck to chin, throat and upper breast enclosing conspicuous large white ear-patch (can be tinged yellow at rear); sometimes chin to upper breast slightly duller and paler than face, and breast can be finely flecked with grey; remiges have olive-yellow edges (broad panel on closed wing, contrasting little with rest of wing and

upperbody), and uppertail has diffuse yellow-olive sides; underbody mottled with dark grey (except on centre of belly); underwing yellowish, mottled with grey on median and greater coverts, and with grey-olive trailing edge and tip; iris red-brown; bill black, gape black to grey-black; legs grey-black. Sexes alike in plumage, male larger than female. Juvenile is much duller and browner than adult, cap and hindneck dark olive and diffusely streaked brown, face and bib dark brown to brownish-grey, rear ear-patch strongly tinged yellow, upperparts olive-brown with greyer olive uppertail-coverts, underbody duller olive-yellow and mottled darker, bill duller, sometimes dull yellowish or pinkish base of lower mandible, gape pink or dirty yellow and initially swollen, iris dark brown to olive-brown. Races vary little, mainly in size and in tone of plumage: *novaeboracae* is slightly smaller than nominate, upperparts slightly duller olive, underparts slightly duller and paler yellowish-olive, off-white fringes at tail tips narrower; *thomasi* is very similar to previous, differing in duller and greyer-toned underbody with smaller unmarked yellowish patch in centre of belly, also male slightly larger. **VOICE.** Generally noisy (seasonal switch in main calls used). Eight main calls: most frequent “Chew call” and “Two-note call”; “Clock call”, “One-note call” and “Scolding” used often; “Rapid Clock”, “Trill” and “Chip” infrequent. Chew call of “chew” or “choor” repeated 1–8 times (two and three repeats most common), used in variety of circumstances, including while foraging and when perched, and Two-note call of double-note syllables repeated 1–8 times (two and three repeats most common), “tch-tchew, tch-tchew, tch-tchew” used in same circumstances as previous (significant temporal differences in use of these two calls; decline in use of chew and increase in use of two-note correspond with start of breeding, and peak use of two-note in late winter and early spring corresponds with peak of breeding.) One-note call of single-note syllables repeated 1–8 times, with no apparent seasonal trends in use. Clock call of single syllables repeated rapidly, sounding like “clock-clock-clock-clock-clock...”, during foraging and when perched, often when partner nearby; peak use when switching from chew to two-note calls, which also precedes start of breeding. Rapid-clock similar to preceding call (possibly better considered a variant of it), but syllables repeated more rapidly; given infrequently over year. Quiet trill occasionally during interactions at territorial boundaries, aerial chases, during interactions between partners, and occasionally when interacting with young. Chip call a single-note vocalization, similar to scolding, given during foraging, more often when other birds nearby. Scolding a brief, broad-band call, typically in long bouts, often when foraging or when alarmed, including among other vocalizations. Other calls include very loud single or double “tchoo” (probably same as first two of above-described eight main calls); occasional “little bubble of song” and a chortle; liquid “quilt” during foraging; and frog-like call (which seems inappropriate for any known calls of this species).

Habitat. Dry woodlands and open forests dominated by eucalypts, usually where trees have decorticated bark on trunks and branches, and with dense well-developed shrub understorey (including heath), and widespread in mallee woodlands, shrublands or mallee heath; less often in dry eucalypt forests and woodlands with grassy understorey (probably not when breeding, for which requires shrub layer). Recorded also in dense regrowth within eucalypt forest and woodlands. In study in Victoria, presence significantly associated with trees having large amounts of decorticated bark, high density of scent bark (*Eucalyptus aromaphloia*) stems, and low level of eucalypt dieback. In E Australia, also commonly in damp and wet sclerophyll forests dominated by eucalypts such as mountain ash (*Eucalyptus regnans*). Also coastal heathlands and tree heaths, especially where adjoining forests or woodlands; *Banksia* or *Angophora* woodlands or shrublands with heath understorey; and semi-arid *Acacia* shrublands or woodlands of lancewood (*Acacia shirleyi*) and brigalow (*Acacia harpophylla*). Occasionally in paperbark (*Melaleuca*) and tea-tree (*Leptospermum*) shrublands and thickets, or forests of cypress-pine (*Callitris*); very occasionally foraging in mangroves. Rarely in agricultural areas, but enters orchards and vineyards and rural gardens. Very rarely in exotic plantations of pines (*Pinus*), usually with understorey of native vegetation. Coasts and lowlands to high altitudes, including to tree-line in Southern Highlands (New South Wales).

Food and Feeding. Mainly invertebrates (insects, also spiders), as well as nectar, lerp, manna and honeydew, and some fruit; estimated ratio of insect-feeding to nectar-feeding in two studies 89:11 and 72:27:5. At some sites, feeds mostly on honeydew of psyllids and eriococcids (Coccoidea) and manna, rarely on nectar. Forages at all heights, from ground to canopy, but often in subcanopy of trees and in shrub layer; only occasionally aerially or on ground or on fallen timber, but appears to forage more on ground in semi-arid regions. Forages mostly on bark, less often foliage, fruits and buds, eucalypt seed capsules, or flowers. Mainly in *Eucalyptus*, exploiting non-eucalypts often only when in flower. Probes beneath, or gleams from, loose, peeling or hanging bark, and probes crevices in rough-barked species such as bloodwoods (*Corymbia*); gleams from foliage; takes nectar from flowers by probing; occasionally takes fruit, including in orchards and vineyards, or takes insects by sallying (sally-strikes in air for flying insects, sally-strikes on twigs and foliage) or pouncing. Feeds at wounds in trunks and branches, including on exudate from *Acacia*. In S South Australia (including Kangaroo I), most food taken from bark was honeydew of coccids. Normally in twos (usually pairs), less often singly (partner often not far away), occasionally in small family parties. In much of range, pair maintains large permanent all-purpose territory, but sometimes gathers at sources of abundant food; occasionally joins mixed-species flocks. Can be aggressive towards other species.

Breeding. Recorded in all months, mainly late winter to mid-summer and with resurgence in activity in autumn, most clutches Aug–Dec, and in S Tablelands and Highlands season varies with altitude; re-lays within season, whether earlier attempt successful or failed. Female collects material, accompanied by male, nest a deep and thick-walled open cup, typically neat and firmly woven (some coarsely made), of grass or bark or both, less often plant stems and twigs, leaves, plant down, fine rootlets and moss, bound with spider web and egg sacs and cocoons of spiders or insects, usually deeply lined with mammalian fur or hair (well known for habit of collecting hair or fur from live mammals, including from people), less often with plant down or fibres, bark, feathers, fine grass and artificial fibres; external diameter 8.9–10.2 cm, depth 4–8.9 cm, internal diameter 5–6 cm, depth 3.8–4.5 cm; usually suspended, sometimes supported, often in small vertical fork or upright branches in live shrub or low tree, occasionally grass tussock (usually sheltered by overhanging vegetation), fallen branches, epicormic growth from trunk of burnt tree, once between dead mallee stem and peeling bark, typically bound to twigs and branches by grass stems and leaves; nearly always close to ground, in one study at 0.2–9 m (mean 1 m), and recorded as low as c. 15 cm above ground in grass

tussock. Clutch usually 2 eggs, occasionally 3 and infrequently 1 (one nest contained four young), mean 2.09; incubation of eggs and brooding of young by female only, nestlings fed by both parents; combined incubation and nestling periods at one nest 28–32 days; fledglings fed by both parents. Nests parasitized by Fan-tailed (*Cacomantis flabelliformis*) and Pallid Cuckoos (*Cuculus pallidus*) and Horsfield’s (*Chrysococcyx basalis*) and Shining Bronze-cuckoos (*Chrysococcyx lucidus*). From 52 eggs in 26 nests, 0.31 fledged young per nest; of 40 nests, 45% fledged at least one young.

Movements. Resident; some local movements. Partial altitudinal migration in highlands of SE Australia: recorded at all altitudes below tree-line throughout year, but numbers at different altitudes change seasonally, with descent from high country in winter and subsequent increase in abundance at lower altitudes (including coastal SE Australia), and return in later winter–spring; e.g. in Australian Capital Territory, above 1300 m less common in mid-winter but populations re-established by Oct, at 1100–1300 m common at all times, below 1100 m marked increase from late Mar through winter and starts to return to higher altitudes about Aug. Extent of other observed movements not known, e.g. irregular or vagrant in some regions, and occasional influxes or congregations in response to flowering of *Eucalyptus*.

Status and Conservation. Not globally threatened. Fairly common but somewhat patchily distributed, e.g. nominate race largely absent from coastal areas of SE Queensland (S of Rockhampton) and NE New South Wales (S to Central Coast). No estimates of global population, but recorded densities of up to 1.8 birds/ha and mean densities of up to 1.3 birds/ha. Appears to have declined in Wheatbelt of SW Australia as a result of extensive land clearance; may have declined in E Victoria (E Gippsland). Thought not to fly readily over large open spaces. Has been claimed that loss of native mammals after European settlement created shortage of nesting material, explaining this species’ penchant for taking hair from humans.

37. Yellow-throated Honeyeater

Lichenostomus flavicollis

French: Méliophage à gorge jaune **German:** Gelbkohl-Honigfresser **Spanish:** Mielero Cuelligualdo

Taxonomy. *Melithreptus flavicollis* Vieillot, 1817, Nouvelle Hollande = King Island, Bass Strait, southern Australia.

Forms a superspecies with *L. leucotis*. Monotypic.

Distribution. Tasmania and islands in Bass Strait (King I and Furneaux Group).

Descriptive notes. Male 20–23 cm, 18–40 g; female 18–20 cm, 22–33.5 g. Plumage is bright olive-green above, with dark silvery grey head and neck, and bright yellow chin and throat; grey-black forehead, lores, malar area and ear-coverts continuous with diffuse narrow blackish band across bottom of throat-patch, and merging into fine blackish streaking on top of head and neck; diffuse silvery patch behind and below eye, small pale yellow patch on rear ear-coverts; edges of remiges and rectrices slightly brighter yellow-olive than upperparts; breast dark grey, grading to paler grey belly, vent and flanks with olive wash, and diffusely mottled

darker throughout; undertail-coverts dark grey-brown, mottled with yellow, undertail dull greyish-olive; underwing buff-yellow, merging to dark grey on trailing edge and tips and with yellow leading edge of coverts; iris reddish-brown, sometimes dark orange to pale brown; bill black, gape black to dirty pink or dirty yellow; legs grey-black, soles paler. Sexes alike in plumage, male larger than female. Juvenile is slightly duller than adult, with brown wash on top of head, hindneck and mantle, grey of neck merging into olive of upperparts (not sharply demarcated), paler and greyer malar area and anterior ear-coverts, paler and less uniform throat, pink-buff or yellow gape, and duller red-brown to straw-yellow iris. **VOICE.** Loud and powerful. Eight main vocalizations, with “Trill” and “Tonk song” heard throughout year, most often in non-breeding season, and “Breeding song” in breeding season; all three used in territorial advertisement or mate attraction. Breeding song varies geographically. Most common vocalization is tonk song, a loud, resonant “tonk, tonk, tonk” or whistled “tchook, tchook, tchook...” or “chock-chock-chock...”, at Mt Nelson, mean of 4 notes per song. Breeding song a loud “de-witt” or whirling “churuk-churuk...”, usually repeated 3–4 times in a bout, sometimes only once or in bouts of up to six; at Mt Nelson, mean of 7 notes/song. Male gives tonk and breeding songs more often and more loudly than female. Trill a warbling trill or rattling repetition of same note, or low running notes; at Mt Nelson, mean 15 notes/song. “Churr” (or aggressive call) a harsh “kra-kra-kra”, often in flight and by both sexes, associated with agonistic interactions or territorial behaviour. “Challenge call” harsh and high-pitched, of rapidly repeated notes, during fights with conspecifics. Harsh high-pitched “Squeal” by male during distraction display. “Cheep” by intruding female when chased from territory. Harsh “Food call” of rapidly repeated notes, by female when approaching with food, by both sexes when feeding fledglings. Other vocalizations include soft version of breeding song, usually alternating with cheep, by female when attempting to collect hair for nesting; and purring call from incubating female. Snaps bill during agonistic interactions.

Habitat. Dry and wet sclerophyll forests dominated by eucalypts, including dry eucalypt forests with understorey of sclerophyllous shrubs or grassy ground layer, and damp to wet sclerophyll forest with understorey of either sclerophyllous shrubs or cool-temperate rainforest elements. Less often in open eucalypt woodland or subalpine eucalypt forest, usually with diverse (often heath) shrub layer; cool-temperate rainforest; coastal and riparian heathlands or closed wet shrublands dominated by *Eucalyptus*, *Banksia*, *Hakea*, *Leptospermum*, *Acacia*, casuarina and grass-trees (*Xanthorrhoea*) and other heath species. Commonly in urban areas and towns, in parks, gardens and reserves. Rarely, in buttongrass (*Gymnoschoenus sphaerocephalus*) sedgeland or heath-sedgeland with scattered eucalypts; alpine *Poa*

grassland and lower-altitude hermland; and low coastal scrub. Sometimes in orchards, and in cleared or partly cleared land, including agricultural land. Sea-level to c. 1550 m, mostly below 1000 m.

Food and Feeding. Arthropods (insects, some spiders), also nectar and fruit, possibly seeds. Forages at all levels, from canopy to, rarely, ground; mainly in large trees, as well as in saplings, shrubs and among litter or herbs on ground; once among reeds. Searches twigs, branches and foliage, mainly in canopy and on trunks of large trees. Main methods are gleaning from surfaces of bark and foliage, or from ground, and probing beneath loose bark of branches and trunks; often sallies for flying insects, sometimes pulls at bark. Only occasionally forages at flowers, taking insects and occasionally probing for nectar. When foraging on bark, prefers large trees with greater surface area. Agile; often hangs upside-down. Usually singly or in twos (probably mostly pairs) throughout year, occasionally in family groups; may congregate in small groups at abundant sources of food. Aggressively defends resources against conspecifics and other species, especially other honeyeaters; in non-breeding season, flocks of smaller *Melithreptus* can overrun territories of present species.

Breeding. Season late winter to mid-summer, mainly Sept–Nov, clutches recorded Aug–Dec. Female collects material and builds nest, usually a small open cup, sometimes deeper and more substantial, of grass and strips of bark. Sometimes bound with spider web, thickly lined with fur or, less often, wool, hair, fine grasses or bark, plant down or string (often alights on live mammals, including human heads, to pull out hair or fur for nesting material), other materials used for external structure include thin twigs, wool, feathers, lichen, spider egg sacs and string, external diameter 7.6–14 cm, depth 6.5–11.4 cm, internal diameter c. 5–7.6 cm, depth c. 4–6.4 cm; typically supported, occasionally suspended, usually low down, 0.15–7.6 m (mean 1.1 m) above ground, close to centre of dense shrub, grass tussock, rushes or, often, epicomorphic growth from stump or burnt eucalypt, occasionally in tree or fern or in fallen branches or litter. Clutch usually 2–3 eggs, but up to 5 recorded (mean 2.4); incubation by female only, claimed that male once fed mate at nest, incubation period 15–17 days; chicks fed by female, nestling period 16 days; fledglings tended at first by female alone, solely by male if female renests, fed for at least 3 weeks and possibly until end of season; fledglings roost close together. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*).

Movements. Resident, with at least some local movements. Males largely sedentary in permanent territories, but apparent dispersion of at least some females and young at end of breeding season; such movements and dispersion probably basis for claims of nomadism. Unconfirmed report from mainland Australia, on Wilsons Promontory (S Victoria).

Status and Conservation. Not globally threatened. Restricted-range species: present in Tasmania EBA. Fairly common and widespread. No estimates of total population; recorded densities of 0.96–1.19 birds/ha, and mean densities of 0.12–1.97 birds/ha. Formerly considered a pest in orchards growing smaller fruits, such as cherries and currants.

Bibliography. 38. Yellow-tufted Honeyeater
Lichenostomus melanops

French: Méléphage cornu **German:** Gelbstirn-Honigfresser **Spanish:** Mielero Orejigualdo
Other common names: Black-faced/Gippsland Yellow-buffed/Golden-tufted/Spectacled/Subcrested/Yellow-throated Honeyeater; Helmeted Honeyeater (*cassidix*)

Taxonomy. *Turdus melanops* Latham, 1801. Nova Hollandia = region of Port Jackson, New South Wales, Australia.

Closest to *L. cratitius* and *L. keartlandi*. Race *cassidix* formerly considered a separate species by some authors. Birds in E Victoria and SE New South Wales intermediate between latter and nominate, and sometimes treated as intergrades; analysis of microsatellite-DNA variation within species, however, supports their recognition as race *gippslandicus* (and provides no evidence for recent introgression between *cassidix* and *gippslandicus* or *cassidix* and *meltoni*). Four subspecies recognized.

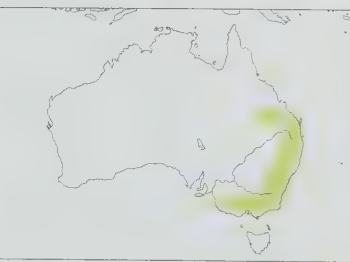

Subspecies and Distribution.

L. m. meltoni (Mathews, 1912) – W watershed of Great Divide, narrowly extending to E watershed of SE Queensland, S to NE & CN Victoria, thence W to border region near South Australia, with outlying populations at high altitude in Snowy R watershed and Mt Kosciuszko region (SE New South Wales).

L. m. melanops (Latham, 1801) – New South Wales E of Great Divide.

L. m. gippslandicus (Wakefield, 1958) – E Victoria (W Gippsland) E to extreme SE New South Wales (Narooma and Eden).

L. m. cassidix (Gould, 1867) – Yellingbo area, in W Gippsland (CS Victoria).

(forming strong panel on folded wing); uppertail olive, yellow-olive sides and broad white tip on outer feathers (lost with wear); underparts olive-grey, washed yellow, diffusely streaked yellow across breast; underwing buffish-yellow with olive-grey trailing edge and tip; undertail olive-grey with yellow-olive sides and white tip; iris rufous-brown to rich red-brown; bill and gape black (in non-breeding periods some develop traces of yellow on gape and faint grey or yellowish base of lower mandible); legs grey. Sexes alike in plumage, male slightly larger than female. Juvenile is duller and paler than adult, with brownish-black mask, paler yellow ear-tuft and malar area, brownish downy feathers on back and rump, black-brown to black bill with yellow or orange base of lower mandible, yellow and swollen gape, and dark brown iris. Races differ in size and plumage: *meltoni* is like nominate, differing only in smaller size, slightly less dark hindneck to back, and slightly narrower pale tip on outer rectrices; *cassidix* is highly distinctive, both sexes significantly larger than others (estimated 7–17% larger than previous race in linear dimensions and 40–43% heavier), forehead feathers elongated and forming richer yellowish crest, otherwise differs from nominate and previous in much broader and (on some)

longer black mask, longer ear-tuft, yellow-olive nape and hindneck (grading into or sharply demarcated from black-brown mantle), much darker upperside, black wash on throat in some birds, richer yellow belly and streaking on breast, and (in fresh plumage) broader white tips of outer rectrices; *gippslandicus* is intermediate between nominate and last in plumage, closer to last in size. **Voice.** Complex and varied, and some listed calls possibly variant descriptions of others. Some calls harsh and scratchy, others clear and almost whistling. Contact call “tsup”, “shup”, “jik”, “chow” or “scow”, sometimes used also in alarm. Other alarm calls include single or repeated “see”, varying in pitch and intensity, may be given by several birds in response to bird of prey; sometimes also as contact during strong winds (when single-note contact would not be heard); variant, described as sharp “peep”, as alert call (e.g. by male to female on nest). Various soft notes in social contexts, and often during corroborees (see page 534); and very soft conversational warble, “jor, jor, jor, jor, jor, jiree, jiree, jiree, jiree” or as “twee, twee, twee, twee, coffee-coffee-coffee-coffee”, repeated 2–3 times, typically between pair-members at nest, when human observer near young and (a louder version) during corroborees; soft indistinct “weet-weet-weet...”, usually of 4–5 notes, appears to be a territorial call. Other calls include repeated “char, char, char...”, often for long periods or interspersed with “see” calls, possibly same as harsh “churl, churl, churl...”; scolding note by adults attacking own young or when potential threat nearby; harsh scolding “chuzz-uzz” or “chuzz-uzz-uzz-uzz” when alarmed; incessant loud chattering during mutual chasing; low melodious trilling in flight; and harsh low continuous “tooyey-t-tooyey-t-tooyey-t...” trill during corroborees. Snaps bill in aggression.

Habitat. Dry open sclerophyll forests and woodlands, typically dominated by eucalypts and with well-developed, often dense, understorey; frequently in riparian associations, along watercourses or in or bordering swampland, or vegetation near water. Nominative race, *meltoni* and *gippslandicus* mainly in mixed eucalypt associations, especially box–ironbark forests or woodlands, e.g. of mugga (*Eucalyptus sideroxylon*) and grey box (*Eucalyptus microcarpa*), but in range of combinations of box, stringybark, gum and peppermint eucalypts and *Angophora*, and often confined to riparian associations; recorded also in mixed eucalypt–cypress-pine (*Eucalyptus–Callitris*) woodland, and sometimes woodlands dominated by cypress-pines or in mallee associations. Nominative race also inhabits communities dominated by *Banksia*, and heathland, very occasionally forages in coastal *Leptospermum* shrubland or among mangroves, and sometimes visit gardens. In some areas moves from open forest with dense understorey to wooded gulleys in autumn–winter, or shifts into different habitats (e.g. nominate race often uses heathland with flowering *Banksia* in autumn–winter). Endangered race *cassidix* largely confined to narrow remnant strips of tall riparian forest and woodland dominated by mountain swamp gum (*Eucalyptus camphora*) on flats along streams or surrounding swampland, with tall dense understorey of scented paperbark (*Melaleuca squarrosa*) and woolly tea-tree (*Leptospermum lanigerum*), or reeds or sedges; in winter, some movement to nearby terraces or slopes with more open forest dominated by swamp gum or mixed green scent-bark–messmate–narrow-leaved peppermint (*Eucalyptus fulgens–E. obliqua–E. radiata*), with diverse dense heath understorey; formerly also in tall open riparian manna gum forest on less swampy sections of creeks, and recently reintroduced into this habitat.

Food and Feeding. Primarily arthropods (mainly insects, some spiders, occasionally gastropod snails) and insect products, such as lerp and honeydew, as well as nectar and manna; occasionally fruit. Race *cassidix* commonly feeds on exudate flows from injuries on trunks of eucalypts. Forages mainly in canopy of tall trees (typically eucalypts), less often in subcanopy, in saplings and shrubs, occasionally on ground; *meltoni* fed mainly in trees (c. 77–92%), with rest in shrubs or on ground, but in other studies foraging done almost equally at all levels. Frequently forages among foliage, twigs, and on exfoliating or decorticating bark on small and large branches and trunks of trees, or feeds aerially; occasionally at flowers. In studies of race *cassidix* at Yellingbo, foraging comprised only 16% of general behaviour, and in one case foraged almost wholly in trees (c. 95–97% of observations of non-nectar-feeding), with remainder in shrubs; foraging height varied seasonally, much time spent in lower strata during Mar–May, and most in upper strata in Jun–Oct; this race specializes on foliage and bark of eucalypts, taking mainly arthropods and sugary exudates, and tends to feed on nectar and aerially more often in non-breeding season. All races obtain most food by gleaning from foliage and bark, by probing bark, and by sallying for insects (sally-striking both in air and on foliage) or sally-hovering to take manna from tree trunks; only occasionally probe flowers, both for nectar and to obtain insects, or glean from ground litter. Sometimes licks sap from wounds made by Leadbeater’s possums (*Gymnobelideus leadbeateri*) on branches or trunks of paperbarks and tea-trees. Active, conspicuous. Gregarious, usually in pairs or in small to large groups; in non-breeding season also in larger mobile flocks, exceptionally of up to 100 or more individuals at food. Aggressive towards most avian species, especially other honeyeaters.

Breeding. Breeding recorded in all months, though rarely May–Jun, most clutches in Sept–Nov; at Yellingbo (race *cassidix*), early nests finished late Jul and eggs early Aug to mid-Feb (most mid-Aug to Jan); multi-brooded, usually renesting rapidly after failure or success, mean of three nesting attempts per territory per season. Breeds in pairs, sometimes co-operatively and often colonially; breeding colonies, or “neighbourhoods”, composed of birds in several adjacent territories, at least some of which persist throughout year (some known to exist for at least several decades), but permanence varies, possibly with variation in food and weather. Nest often built by female alone, occasionally by both pair-members, a tightly woven cup of grass, pieces of bark, spider web and egg sacs and, less often, plant down, twigs, leaves, wool, fur or hair, feathers, lichen and moss, and roots or rootlets, usually lined with plant down or bark or, sometimes, feathers, fine grass, fur or wool, and leaves; race *cassidix* external diameter 7.8–11 cm, depth, 6.2–10.2 cm, internal diameter 5.7 cm, depth 6 cm, other races combined external diameter 6.4–10.2 cm, depth 5.7–10.2 cm, internal diameter 3.8–6.4 cm; depth 3.8–5.1 cm; usually suspended, sometimes supported (very occasionally on ground), in living or dead understorey shrub, less often in tree, sapling, epicomorphic growth or fallen branches, ferns, grass tussock, nest of *cassidix* generally in dense shrubby thicket and often over standing or running water (usually no more than 0.5 m deep); throughout range nest 0.05–1.6 m (mean 1.4 m) above ground, *cassidix* 0.5–7 m (mean 2.2 m). Clutch usually 2 eggs, occasionally 1 or 3, and once four young recorded in nest, mean 1.98 (*cassidix* mean 2.01); incubation mostly or solely by female, fed on nest by male, period 14–16 days; chicks brooded by female, fed by both sexes and by any helpers present, nestling period from 10 days (probably minimum period) to 16 days, probably usually 10–14 days; fledglings fed by breeding pair and any helpers, mostly independent after 6 weeks of age, but fed sporadically up to at least week 14. Nests parasitized by Fan-tailed (*Cacomantis flabelliformis*) and Pallid Cuckoos (*Cuculus pallidus*) and Shining Bronze-cuckoo (*Chrysococcyx lucidus*). From 128 eggs in 65 nests, 0.11 fledged young per nest, and of 89 nests 24.7% fledged at least one young; of 62 nesting attempts by race *cassidix*, 59.7% produced at least one fledged young, mean productivity of nests with eggs 0.53 young fledged and 0.48 young raised to independence.

Movements. Largely sedentary, with some local movements; altitudinal migration in S. Race *cassidix* sedentary, with some local movement, mainly in winter and mainly by immatures and non-territorial adults, but also involving a few breeding females (which may disperse up to several kilometres, but usually return to same mate and territory in following breeding season). Other races also sedentary, again with some local movements, e.g. in Sydney moves in autumn from forest breeding habitat to heathland; abundance fluctuates at some sites, and apparently some movements occur, seasonal in some areas and irregular in others (latter often described as nomadism), though extent of such movements not known and possibly local or post-breeding dispersal. Some movements (especially by

race *meltoni*) related to climate, particularly drought; *meltoni* occasional vagrant S of Great Divide, including at Yellingbo (range of *cassidix*), at least 50 km S of nearest known breeding site. Altitudinal migrant in Southern Highlands (New South Wales), moving to lower levels in May–Aug.

Status and Conservation. Not globally threatened. Race *cassidix*, sometimes treated as separate species, listed as “endangered” nationally and “critically endangered” in Victoria; CITES I. Locally common in most of range; no estimates of total population of species. Race *meltoni* recorded at densities of 12–5 birds/ha. Population of *cassidix* in 2000 contained 37 breeding pairs (and 36 fledglings produced); densities of up to 6 breeding birds/ha. This race now confined to small section of creek-line (of c. 5 km²) near Yellingbo, but formerly occurred throughout much of SW Gippsland along tributaries of middle Yarra R (area of 2000–3000 km²); three of the four remaining populations have almost certainly become extinct since 1983. This race has declined primarily as a result of habitat loss following clearing for agriculture, which produced a cascading series of impacts: clearance of natural habitat changed patterns of runoff, subjecting remnant trees to increased levels of stress and making them more susceptible to infestation by defoliating psyllids, which, in turn, encourages colonization by *Manorina melanophrys*; latter species causes *cassidix* to spend increased amounts of time in defending territories, possibly leading to reduced breeding success. At Yellingbo, *cassidix* visited nearby areas immediately after *Manorina melanophrys* had been culled, and established territories within 6 months. An artificial levee in Cockatoo Swamp, within Yellingbo, caused channelization and subsequent erosion and sedimentation of a section of Cockatoo Creek, leading to dieback of vegetation at a major colony in 1990s, resulting in twelve territories being abandoned, becoming non-breeding territories, or being incorporated into larger breeding territories of other birds; populations of *Cardinia* Creek and Cockatoo ultimately extirpated by bushfires in Feb 1983. Replanting of suitable vegetation at Yellingbo began in 1978, and the honeyeaters have foraged and bred in these revegetated areas. Population of *cassidix* lives within the Yellingbo Nature Conservation Reserve. A captive management programme was established in 1989; in 2000 there were 35 birds in captivity.

39. Purple-gaped Honeyeater

Lichenostomus cratitius

French: Méliphage grisé **German:** Purpurzügel-Honigfresser **Spanish:** Mielero de Boqueras
Other common names: Lilac-wattled/(Victorian) Wattle-cheeked/Mountain Purple-gaped Honeyeater

Taxonomy. *Ptilotis cratitius* Gould, 1841, interior of South Australia and Kangaroo I = Kangaroo I, South Australia.
Probably forms a superspecies with *L. keartlandi*. Type locality was formerly assumed to be mainland South Australia (either “interior of South Australia” or “Upper Torrens” R), but is, in fact, Kangaroo I; mainland populations thus belong in race *occidentalis*. Name *halmaturinus* (type from Kangaroo I) is therefore a synonym of nominate. Two subspecies recognized.

Subspecies and Distribution.
L. c. occidentalis Cabanis, 1851 – mallee from S Western Australia (area from Wheatbelt E to Kalgoorlie, S to Albany and Cape Arid) E, discontinuously, to S South Australia and the SW Murray–Mallee E to NW & NC Victoria.
L. c. cratitius (Gould, 1841) – Kangaroo I, off South Australia.

and throat; upperparts rather dark olive-grey, slightly browner on upperwing-coverts, which also faintly margined paler; broad yellow-olive outer edges of remiges (distinct panel on folded wing); uppertail brown with olive edges, and fine white tip when fresh; underbody largely olive-grey, diffusely streaked dull yellow-olive, with dull yellow centre of belly; undertail olive-grey, underwing off-white to pale grey with broad brownish-grey trailing edge and tip; iris dark brown; bill black, gape and gape-stripe purple (colour apparently less intense when not breeding); legs grey-black. Sexes similar in plumage, male slightly larger than female. Juvenile is very similar to adult, but facial pattern duller, with eyestripe brownish-black and submoustachial stripe paler yellow, upperparts tinged brownish, some upperwing-coverts with yellow-brown fringes (appearing more scaly), underparts paler yellowish, bill duller, with yellowish base, gape yellow (not purple). Race *occidentalis* is smaller than nominate, also slightly brighter and paler above and below, e.g. underbody greyish-olive to yellowish-olive, with yellow centre of belly, breast faintly streaked slightly darker, flanks and lower regions diffusely streaked pale yellow. Voice. Sometimes noisy; at Eyre Bird Observatory (Western Australia) most vocal Sept–Oct. Vocalizations include rapidly repeated loud chattering “chuc-chuc-chuc-chuc”, during distraction displays and possibly in advertising and defence of territory; scolding in response to potential threats (possibly same as chattering); single harsh “chirp”; loud whip-like whistle; soft warbling like that of a parrot (Psittacidae); sharp unmusical “twit-twit” in flight; and jerky rattling notes. Said also to have pleasing song and a call like one given by *Manorina melanocephala*, both of which may refer to one of preceding vocalizations.

Habitat. Mallee eucalypt associations, preferring mallee heathland, but also often in mallee woodland and shrubland, including remnants in agricultural land or beside roads, and usually with dense

Descriptive notes. 16–19 cm; male 19.5–24.7 g and female 15.5–22.5 g (*occidentalis*), four males 12.5–23.2 g and two females 17–19 g (nominate). Nominat race has distinctive head pattern of dark grey top of head and neck (faint blackish scaling on crown), black eyestripe extending from bill to well behind eye, merging with grey anterior ear-coverts, yellow tuft on rear ear-coverts (can be partly covered by dark anterior ear-coverts), purple gape-stripe (gape and fleshy continuation of gape) extending along bottom edge of eyestripe (often inconspicuous in field), bright yellow submoustachial stripe, and olive-yellow chin

shrubby understorey of heath plants, such as broombush (*Melaleuca uncinata*) or, sometimes, spinifex (*Triodia*); often in thickets of broombush associated with mallee. In some areas, found in non-mallee sandplain heaths and shrublands (e.g. Western Australia), in dry sclerophyll forest or woodland dominated by eucalypts and usually with heath understorey (e.g. Kangaroo I), and in riparian eucalypt or paperbark (*Melaleuca*) associations.

Food and Feeding. Invertebrates (mostly insects, including psyllids and coccids; some spiders) and nectar (frequently of *Eucalyptus*, *Banksia*, *Adenanthos* or other proteaceous or epacrid shrubs); also lerp and honeydew; also some fruit, e.g. of ruby saltbush (*Rhagodia*), and seeds. In one study, proportion of nectar to insects in diet 38:62. Forages fairly low in trees and shrubs, frequently among foliage or at flowers, including occasionally those of mistletoes (Loranthaceae), as well as beneath loose bark of outer branches of trees and in air; occasionally on ground. Feeds on nectar from non-eucalypt sources more on Kangaroo I than on mainland. Invertebrates gleaned from foliage, bark and ground, in aerial sallying, and taken by probing; nectar taken by directly probing flowers. In one study, sallied and gleaned in almost equal proportions. Can be acrobatic when foraging. Usually singly, in twos or in small groups of up to 10–12 individuals, sometimes in larger groups of up to 30 or more at abundant food, such as flowering mallee. Aggressive towards smaller and other medium-sized honeyeaters, e.g. *Acanthorhynchus*, and Silvereyes (*Zosterops lateralis*).

Breeding. Mainly spring and autumn, apparently also unseasonally after rain; clutches recorded Aug–Nov, Jan and Mar–Apr. Nest built probably by female alone (claims that both sexes contribute possibly due to observations of male accompanying female), a deep and compact cup, small for size of bird, usually of woven grass and fine shreds of bark, sometimes small sticks, bound with spider web and egg sacs, lined with wool, fur, fine grass, spider web, a few small feathers or, occasionally, plant down, external diameter 7–8.9 cm, depth 7.6–10.1 cm, internal diameter 5.1–6.4 cm, depth 5.1 cm; 0.5–3 m (mean 1.2 m) above ground in small shrub or, less often, small tree or mistletoe, usually suspended from foliage, fine twigs or fork of horizontal branch, sometimes partly suspended and partly supported, or in vertical fork. Clutch usually 2 eggs; incubation period c. 13–14 days; chicks fed by both sexes, no information on duration of nestling period.

Movements. Resident, with local movements in response to food availability, particularly flowering eucalypts. Sporadic outside usual range, sometimes in large numbers. Seasonal increase in reports near Eyre Bird Observatory, in Western Australia, in Sept–Oct possibly a result of increased conspicuosity, but influxes sometimes recorded there. Reports from Northern Territory and Queensland erroneous.

Status and Conservation. Not globally threatened. Uncommon. No estimates of total population; recorded densities of 0–0.2 to c. 5 birds/ha. Numbers have declined following clearing, degradation or fragmentation of habitat, especially loss of understorey; also overharvesting of broombush, and, at least in short term, fire. Range has contracted in Western Australia.

40. Grey-headed Honeyeater

Lichenostomus keartlandi

French: Méliphage à tête grise **German:** Grauscheitel-Honigfresser **Spanish:** Mielero Cabecigrís
Other common names: Keartland’s) Honeyeater

Taxonomy. *Ptilotis keartlandi* North, 1895, McMinns Range, central Australia.
Probably forms a superspecies with *L. cratitius*. Monotypic.
Distribution. NC Western Australia (S Kimberley Division and Pilbara) E to SW Northern Territory (E to NW Simpson Desert, and patchily in N around Victoria R and in subcoastal S Gulf of Carpentaria to Barkly Tableland), NW South Australia and W Queensland (S of Mt Isa, and in upper Cooper Creek Drainage Basin; apparently isolated population near Eulo).

Descriptive notes. 13–16.5 cm; male 13–17 g, female 12.5–18 g. Has pale grey top of head grading to light grey-brown on hindneck and upperbody, slightly browner on rump and uppertail-coverts; dark mask (formed by grey-black lores, eyering and feathers behind eye, and grey ear-coverts diffusely edged black at rear), which can appear almost wholly black or contrastingly black and grey (depending on light); pale yellow moustachial stripe that meets bright yellow neck-plume extending from below rear ear-coverts and up behind rear of mask; pale yellow chin and throat; upperwing olive-brown, diffusely mottled brown on coverts, fine

white tips on greater secondary coverts, dull yellow-olive outer edges of remiges (yellowish panel on folded wing); uppertail dark olive-brown with dull yellow-olive sides, fine white tip when fresh; breast, belly and anterior flanks yellow with light brown streaking, merging into pale buff-yellow on rest of underbody; underwing pale orange-buff with broad grey-brown trailing edge and tip, undertail grey-brown with off-white tip (in fresh plumage); iris dark brown, dark grey orbital ring; bill and gape black, yellow or buff base of lower mandible and yellow gape when not breeding; legs pinkish-brown. Sexes alike in plumage, male slightly larger than female. Juvenile paler than adult, with rather uniformly grey and less contrasting mask (only indistinct dark line at rear), much paler yellow neck-plume, grey or brown-black bill with orange-yellow to pink-brown base of lower mandible, yellow to orange gape, pinkish-brown orbital ring. Voice. Not well known. Calls frequently, particularly when foraging. Loud, penetrating and rather peevish “chip”; bubbling or lightly trilling song, which may be given in flight; loud deep “kwoyt-kwoyt-kwoyt”; “kew-kew-kew-kew” or “peep-peep-peep”; and “chee-toyt” or “chutoyt” call, thought to be uttered only when breeding. Snaps bill in agonistic interactions.

Habitat. Mainly low, open, arid and semi-arid woodlands, typically in sandstone ranges but also on tablelands and plains, and usually dominated by stunted or mallee eucalypts or with *Acacia*, such as mulga (*Acacia aneura*), or *Grevillea wickhamii*, co-dominant or in understorey; and riverine woodlands dominated by *Eucalyptus*, *Lophostemon* or *Erythrina*, often with dense shrub understorey. Less often in low open mulga woodland, occasionally in *Astrelba* grasslands.

Food and Feeding. Invertebrates (mostly insects, also spiders) and nectar, occasionally fruit. Proportions of observations comprising foraging for nectar 35% in one study, less than 5% in another.

Forages at flowers of wide variety of trees and shrubs (especially *Grevillea*, *Eucalyptus*, *Hakea*, *Lophostemon* and *Erythrina*), in foliage and on large branches of trees and shrubs; insects taken by gleaning from foliage, bark or in shrubs, and by sallying; nectar taken by probing flowers. Active, noisy, often approachable. Usually in twos (probably pairs) or in small groups of 5–6 individuals; occasionally in loose parties of up to 20 or more. Seen to forage with *L. virescens* and *Lichmera indistincta*; six individuals drank from pool with Painted Finches (*Emblema pictum*).

Breeding. Recorded in all months, probably mainly winter–spring, although suggested as breeding at any time after rain; clutches Jan–Feb, Apr–May, Jul and Oct–Feb, and nestlings Apr and Jul–Sept; probably single-brooded. Nest an open, compact cup of dried grass and plant stems and fine strips of bark, bound with spider web and cocoons, lined with plant down, fine rootlets, hair, feathers or spider egg sacs, one had external diameter 6.4 cm, depth 4.4 cm, internal diameter 5.1 cm, depth 3.2 cm; usually (not always) suspended by rim from horizontal fork or among twigs or drooping foliage low in live tree or shrub or mistletoe (Loranthaceae), twelve nests 0.6–3.5 m (mean 1.4 m) above ground. Clutch usually or always 2 eggs; no information on incubation and nestling periods; both parents tend fledglings. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*).

Movements. Poorly known. Apparently mainly resident, with at least local movements. Occasional influxes at some sites. Widespread scattered records beyond normal range, e.g. at Wyndham and Turkey Creek (in N Western Australia), in Simpson Desert, and in N Flinders Ranges (South Australia).

Status and Conservation. Not globally threatened. Relatively poorly known species, with little information on numerical status. Widespread in N Western Australia and W Queensland. No estimates of population.

Bibliography. Barrett *et al.* (2003), Blakers *et al.* (1984), Burbidge & Fuller (2007), Campbell (1900), Colston (1974), Cooney *et al.* (2006), Ford, H.A. & Paton (1976a), Ford, J.R. 41. Yellow-plumed Honeyeater
Lichenostomus ornatus

French: Méléphage orné **German:** Gelbscheitel-Honigfresser **Spanish:** Mielero Adornado
Other common names: Graceful/Mallee Honeyeater

Taxonomy. *Ptilotis ornatus* Gould, 1838, Swan River, south-west Western Australia.
Forms a species group with *L. plumulus*, *L. fuscus*, *L. flavescens* and *L. penicillatus*. Monotypic.

Distribution. SW Australia (mostly S of 30° S but largely excluding far SW) E to Eyre Bird Observatory (scattered records N of this range), and from E Nullarbor Plain and S Great Victoria Desert E in South Australia (including Eyre Peninsula, Flinders Ranges) to The Coorong and Murray-Mallee and to NW & NC Victoria and C New South Wales.

Descriptive notes. 14–18.5 cm; male 16–22.1 g, female 12.2–21.1 g, unsexed 11–22 g. When breeding, top of head is yellow-olive, grading to olive-grey on hindneck and side of head, with dusky smudge in front of and around eye, narrow dull yellow moustachial stripe, and diffuse black band on rear ear-coverts bordering anterior edge of long bright yellow neck-plume that ends in pointed tuft; upper-body and upperwing dark brownish-grey, grading to grey-olive on rump and uppertail-coverts; yellow-olive edges of upperwing coverts, and bright olive-yellow edges on otherwise brown remiges (bright panel on folded wing, diffuse panel through middle of spread wing); uppertail olive-brown with yellow edges and fine white tip (rapidly lost with wear); off-white below, strongly streaked brown on chin, throat, breast, upper belly and flanks, merging to lighter streaking on lower underbody; undertail greyish-brown; underwing greyish orange-buff, with pale grey bases of all except outer remiges, greyish-brown trailing edge and tip; iris brown, orbital ring black; bill and gape black; legs greyish-brown. Non-breeding as breeding but orbital ring yellow to orange-yellow, and bill black with pale yellow to yellow-orange base and yellow to orange-yellow gape. Sexes alike in plumage, male larger than female. Juvenile is paler and browner than adult, with brownish-olive top of head, short diffuse yellowish supercilium, duller dusky smudge in front of and around eye, less heavily streaked below, black-brown bill with yellow to orange-yellow base (duller than non-breeding adult) and swollen pale yellow to yellow gape. **VOICE.** Can be very noisy; one of first species to vocalize in morning, and heard sporadically through day. Range of loud, clear or harsh and sharp vocalizations. Song brisk chirping “chickwiddee” or loud, ringing “chick-o-wee”; flight song repeated rapid trilled whistles. Contact call repeated “chip” notes. Several alarm calls, including e.g. flat trill and long shrill note, rapidly repeated chirps.

Habitat. Mallee eucalypt woodlands, usually with sparse understorey of *Leptospermum*, *Acacia* and *Eremophila* and ground cover dominated by chenopods. In Western Australia, common also in coastal eucalypt woodlands or forests dominated by tuart (*Eucalyptus gomphocephala*), wandoo (*Eucalyptus wandoo*) or, occasionally, salmon gum (*Eucalyptus salmonophloia*), though not commonly in non-mallee woodlands elsewhere in range. Sometimes in *Acacia* woodlands, e.g. those dominated by western myall (*Acacia papyrocarpa*), or mixed woodlands of cypress-pine-belah (*Callitris-Casuarina cristata*) or *Callitris-Eucalyptus*; rarely, in dense jarrah (*Eucalyptus marginata*) forests in Western Australia.

Food and Feeding. Arthropods (insects, also spiders and mites), nectar (e.g. of *Eucalyptus*, *Banksia*, some Epacridaceae) and lerp, manna and honeydew; occasionally flowers and fruit. Proportion of insect-foraging to nectar-feeding in one study 76:24. Forages mainly in trees (90% of observations in one study), especially eucalypts, and less often in understorey shrubs, only occasionally on ground; at Dryandra (Western Australia), mean foraging height 6.7 m, and 84% of observations in canopy and subcanopy. Forages at flowers, on bark, on twigs, in foliage (particularly outer foliage), in air, and occasionally among leaf litter and bark on ground. In Victoria, mean of 38% of observations of foraging were at flowers, 27% on branches, 9% on twigs, 1% on trunks, 15% in foliage, 10% in air; at Dryandra, 8% at flowers, 44% on bark of branches, 12% on bark of trunks, 20% in foliage, 15% in air. Nectar obtained by probing. Insects gleaned from foliage, bark, infrequently ground; also caught by sallying, mainly sally-striking for flying insects but also sally-striking and sally-hovering on foliage or bark; also by probing under bark, occasionally by pouncing. Appeared to crush ripe fruits of ruby saltbush (*Enchylaena tomentosa*) to extract juice. Usually

singly, in twos (probably pairs) or in small flocks, often of six or more individuals (up to 20) at flowering trees; in NW Victoria, 80% of records were of 1–2 birds. Often aggressive, squabbling, but will co-operate to exclude conspecifics and other species at feeding site. Hundreds may gather in areas with abundant food, or at water, e.g. 650 birds in one area. Where co-occurring with *L. plumulus* latter tends to be dominant, but present species tends to dominate when more numerous.

Breeding. Recorded in all months, apparently least often in mid-summer and late autumn; most clutches (69%) Oct to early Dec. Possible instances of opportunistic co-operative breeding, but circumstances not properly known. Nest a rather shallow open cup usually of woven grass and wool and bound with spider web, sometimes with other materials (e.g. spider egg sacs, flowers, fine fibre, bark strips, rootlets and tufts of wool), lined with wool, fine grasses, plant down and feathers, often unlined, external diameter 6.4–7.5 cm, depth 3.2–5 cm, internal diameter 4.4–5.5 cm, depth 3–3.5 cm; usually suspended by rim from thin horizontal fork or drooping foliage or leafy twigs, frequently in live mallee eucalypt (93% of records in one sample), occasionally supported (e.g. in upright shoots), occasionally in other site, e.g. suspended inside dead spout of live mallee, or in vertical fork against trunk or in mistletoe (Loranthaceae); 0.45–20 m (mean 3.1 m) above ground, 31 nests in Eyre Peninsula 0.76–4.6 m (mean 1.8 m). Clutch 1–3 eggs, usually 2 (mean 2.09); estimated incubation period 12–15 days and nestling period 12–14 days, but no accurate determinations; both adults feed nestlings and fledglings. Nests parasitized by Fan-tailed (*Cacomantis flabelliformis*) and Pallid Cuckoos (*Cuculus pallidus*) and by Horsfield’s (*Chrysococcyx basalis*) and Shining Bronze-cuckoos (*Chrysococcyx lucidus*). For 89 eggs in 44 nests where outcome known, 0.55 fledged young per nest; of 83 nests, 53% fledged at least one young.

Movements. Largely resident over much of range, but at least some local movements. In detailed study at Mt Mary Plains, in South Australia, numbers fluctuated (including lower numbers in spring–summer of some years); movements said to be related to food supply, and possibly involve mainly immature and unpaired birds. Movements elsewhere often said to be associated with flowering of food trees. Occurrence at some sites seemingly unpredictable, and thus described as partially nomadic in some regions. Some shifts seem to be influenced by climatic factors, e.g. in dry years in Victoria moves locally during autumn–winter, with records in S or E regions, and in Adelaide region of South Australia disperses to S in dry years. Large S movement of hundreds of individuals noted once (in May) in W New South Wales. Vagrants recorded beyond normal range, e.g. in South Australia scattered records W of main range and vagrant in investigator Is and on Kangaroo I.

Status and Conservation. Not globally threatened. Locally common. Recorded densities of up to 3.6 birds/ha. Population N of Dubbo, in New South Wales, possibly isolated. Declined in distribution and abundance throughout S of range, with local extirpations, as a result of widespread loss, fragmentation and degradation of habitat for agriculture; apparently unable to persist in highly fragmented landscapes. Requires most productive habitats within a region, but these have been preferentially cleared for agriculture, and small remnants of native vegetation unlikely to contain sufficient expanse of suitable habitat to sustain populations, e.g. was common in Wheatbelt of Western Australia in early 20th century, but now reduced to small populations confined to remnant woodlands. In contrast, range thought to have expanded into SW Western Australia, along Blackwood Valley, after extensive clearing of forests since 1930s.

Bibliography. Anon. (1926), Barrett *et al.* (2003), Blakers *et al.* (1984), Boehm (1957, 1978), Brooker & Brooker (2004), Brooker *et al.* (1979), Campbell (1900), Carpenter & Mathew (1997), Colston (1974), Cooney *et al.* (2006), Deli (1978), Elliott (1916), Emison *et al.* (1987), Ford, H.A. 42. Grey-fronted Honeyeater
Lichenostomus plumulus

French: Méléphage à plumet noir **German:** Grünscheitel-Honigfresser **Spanish:** Mielero de Plumón
Other common names: Plumed/Yellow-fronted Honeyeater

Taxonomy. *Ptilotis plumulus* Gould, 1841, York district, Western Australia.
Forms a species group with *L. ornatus*, *L. fuscus*, *L. flavescens* and *L. penicillatus*. Race *grangeri* intergrades with nominate in narrow zone in CE South Australia (W slopes of Flinders Ranges and Willouran Range), and appears to intergrade with *planasi* in CE Queensland (but few data); uncertain whether *planasi* and nominate intergrade where they meet (in C Northern Territory). Birds from Port Augusta, in South Australia, described as race *ethelae*, which name is sometimes applied to E Australian form; type locality, however, lies within zone of intergradation between nominate race in W and populations in E, and name *grangeri* (type from Mt Grainger, in South Australia) is therefore used for latter form. Three subspecies recognized.

Subspecies and Distribution.
L. p. planasi (A. J. Campbell, 1910) – N Western Australia (S & E Kimberley Division) E across S Top End to N Queensland (S Gulf of Carpentaria–Selwyn Range and, in NE, W of Great Divide).
L. p. plumulus (Gould, 1841) – SW & C Australia from near W coast (between Pilbara region and Geraldton) E to C ranges of S Northern Territory and to EC South Australia (S to E Nullarbor Plain, E to Gawler Ranges and W edge of L Eyre Basin).
L. p. grangeri (Mathews, 1912) – inland E Australia sparsely from CE Queensland (c. 20–21° S) S, E to W fringes of Great Divide, to SW New South Wales and NW Victoria, and through Murray–Darling Basin W to Flinders Ranges of South Australia.

Descriptive notes. 14–16.5 cm; male 13.5–18.5 g and female 15–16.5 g (nominate), male 15–22.5 g and female 16–27.5 g (*grangeri*), male 12–21.5 g and female 11–16.7 g (*planasi*). Nominative race has olive-yellow top and side of head, with inconspicuously grey lower forehead, distinct stripe formed by black-brown lores and eyering, and fine black gape-line meeting black tips of rear ear-coverts, and a short, broad yellow neck-plume that fans out on side of neck; upperparts light grey-brown, tinged yellow; upperwing brown, dull yellow-olive outer edges of secondaries and primaries (large panel on folded wing), fine white tips of remiges and terminal outer edges of primaries; tail grey-olive with yellow-olive sides; off-white

SPECIES ACCOUNTS

PLATE 41

below, yellow wash on chin, throat, breast and undertail-coverts, and diffuse brownish streaking throughout, faintest on breast; underwing cream with brownish-grey trailing edge and tip; iris dark brown; bill and gape black; legs dark blue-grey to dark grey. Sexes alike in plumage, male slightly larger than female. Juvenile is slightly duller and paler than adult, with browner upperbody, paler and less distinct neck-plume, light grey-brown upperwing-coverts with light brown fringes, greyish-brown bill with yellowish to cream base of lower mandible, and swollen yellow to orange gape. Races differ in size and plumage: *grangeri* is significantly larger than nominate, with darker upperparts and (some individuals) darker grey-brown streaking on breast and richer yellow centre of breast, adults from E limit of range tending darker above and with bolder breast streaking (extending to upper belly and over flanks) than those from W; *planasi* is similar to nominate but with longer bill and shorter tarsus, upperbody generally paler, streaking below finer and better defined, grey band on lower forehead much narrower, top of head duller yellow-olive, merging to grey-brown on nape and hindneck, and black line across rear ear-coverts broader. VOICE. Vocalizations described as sharp, shrill, loud, and repeated often, but can be silent for long periods during day. Male song described as canary-like; and flight song a loud, sharp, almost guttural "it-wirt", "wirt, wirt, wirt" or "it-wit it it", given in and after display-flights. Calls include repeated "clit", as contact; harsh squeaking note in alarm or when congregating; twittering calls; harsh screeching; and a "sw-e-e-t".

Habitat. In S mainly mallee eucalypt woodlands or shrublands or associated habitats, and commonly in low, densely coppiced mallee regenerating after fire or harvesting, though infrequently in taller mallee woodlands; and also semi-arid heathland or mulga woodland interspersed with patches of mallee eucalypts. Rarely far from mallee, but recorded in low non-mallee eucalypt woodlands, particularly those close to mallee, and will exploit flowering vegetation near or in ecotone with mallee vegetation. In inland and N Australia mainly in low riparian vegetation, including understorey of taller riverine associations, and savanna eucalypt woodlands or forests, usually with grassy ground layer. Throughout range, recorded also in low woodlands or shrublands dominated by *Acacia* or paperbark (*Melaleuca*). **Food and Feeding.** Nectar, particularly of *Eucalyptus*, *Eremophila* and mistletoes (Loranthaceae), and arthropods (mostly insects, some spiders); also fruit and seeds (latter probably from fruits). Usually forages in crowns of trees (especially mallee eucalypts) or in shrubs, sometimes in air, occasionally on ground. Obtains insects by gleaning from foliage, twigs and bark of larger branches of trees and shrubs, also by sallying above canopy; very occasionally gleans from ground; nectar taken by probing flowers. Usually forages singly, in twos (probably pairs) or in groups of up to c. 15 individuals, occasionally in larger loose flocks of up to 80 birds in areas of flowering trees. Often displaces other meliphagids; variously dominant over or submissive to *L. ornatus*, apparently related to numerical dominance of each species in an area; seen to forage with *L. fuscus* and *L. penicillatus* without aggression.

Breeding. Recorded in all months, but centred on winter-spring; clutches Jun–Mar. At one nest, only one member of pair appeared to build (occasionally accompanied by mate); nest a deep cup, often slightly smaller at rim, usually of fine grass, spider web, plant down or fibre or fine strips of bark, lined with plant down, feathers or hair or fur (other materials used include spider egg sacs, cocoons, and rootlets), external diameter 7–7.6 cm (6.4 cm at rim), depth 5.7–6.4 cm, internal diameter 4.4–5.1 cm, depth 2.5–4 cm; usually suspended (occasionally supported) 0.6–6.6 m (mean 2.3 m) above ground, often in terminal foliage but also from twigs, drooping branch or fork, in live small tree (especially mallee eucalypt) or shrub, occasionally mistletoe. Clutch usually 2 eggs, occasionally 1 or 3; incubation period once 15 days, said also to be 14 days; chicks fed by both sexes, nestling period once 12 days, once 15 days, given also as 14 days; at one nest, incubation of eggs and brooding of young by only one member of pair, probably female; fledglings fed by both adults. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*) and, possibly, Horsfield's Bronze-cuckoo (*Chrysococcyx basalis*). Of seven nests, six fledged at least one young.

Movements. Resident in many places. Numbers can fluctuate, e.g. around Mt Isa, in NW Queensland, numbers highest May–Dec; described as partially nomadic in New South Wales and possibly in Northern Territory, and said not to stay for long at any site in South Australia. No information on causes of fluctuations or extent of any movements. Vagrants of race *planasi* recorded N of normal range in Top End; vagrant *grangeri* recorded E of range.

Status and Conservation. Not globally threatened. Formerly listed as "endangered" in Victoria. Uncommon and rather sparsely distributed; no estimates of population. Adversely affected by clearance of mallee vegetation for agriculture, particularly wheat-cropping, in S of range, but may have benefited from harvesting of mallee for *Eucalyptus*-oil production, which creates areas of coppiced or regenerating mallee.

43. Fuscous Honeyeater

Lichenostomus fuscus

French: Méléphage grisâtre **German:** Olivkehl-Honigfresser **Spanish:** Mielerio Fusco

Taxonomy. *Meliphaga fusca* Gould, 1837, New South Wales = region of Sydney, east Australia. Forms a superspecies with *L. flavescens*, with which formerly often considered conspecific; both are part of a species group that includes also *L. ornatus*, *L. plumulus* and *L. penicillatus*. Races intergrade in fairly narrow region of Dawson–MacKenzie rivers, in CE Queensland; birds from Dawson R described as race *dawsoni*, but represent part of this intergrading population. Two subspecies recognized.

Subspecies and Distribution.

L. f. subgermanus (Mathews, 1912) – E Queensland on and E of Great Divide (from Big–Windor Tablelands SE of Cooktown, S to Dawson–Mackenzie Basin), in NE Australia.

L. f. fuscus (Gould, 1837) – E & SE Australia from Dawson–Mackenzie Basin S to Victoria (W to South Australia border region).

Descriptive notes. 13.5–17 cm; male 12–24 g and female 13.7–19 g (nominate), male 14–20 g and one female 14 g (*subgermanus*). Nominata race breeding is greyish olive-brown above, with smudged blackish-brown ring around eye sometimes extending to lores, small pale yellow neck-plume narrowly bordered black on upper rear edge; olive scaling on upperwing-coverts, dark brown patch at bend of wing; remiges dark brown with yellow-olive outer edges (broad olive panel on folded wing), neat, fine white tips on outer primaries (in fresh plumage); yellow-olive sides of upperpart; chin, throat and breast slightly paler than upperparts, brown-grey, faintly streaked cream to buff, rest of underbody off-white, faintly streaked grey-brown; underwing light grey-brown, darker brownish-grey trailing edge and tip; undertail dull brown with yellow-olive sides; iris dark brown, orbital ring black; bill and gape black; legs grey. Non-breeding plumage as breeding, but base of bill yellow, and cere, gape and orbital ring yellow. Sexes alike in plumage, male slightly larger than female. Juvenile is very similar to

"twit't't't" or "arig arig a", often ending in harsh "taw-taw-taw..."; flight song a deep metallic "tew-tew-tew". Alarm calls include rapidly repeated high-pitched fluting in response to aerial predator; high-pitched twittering, possibly same as call described as short high-pitched "twee-twee-twee", during corroborees (see page 534); a call between last-mentioned and the one for aerial predator, given during chases, when captured or when potential avian predator close to nest; and harsh note or scolding when very agitated or alarmed.

Habitat. Dry, open sclerophyll forests and woodlands dominated by range of eucalypts and with dense or sparse understorey of shrubs or open grassy ground cover, especially box–ironbark, box or bloodwood (*Corymbia*) associations, or spotted gum forests and woodlands, and sometimes in eucalypt associations mixed with cypress-pine (*Callitris*); very occasionally in mallee woodlands. Sometimes also in remnant patches, including linear remnants, such as stock routes and roadside vegetation, in agricultural land or remnant trees in pastoral land; also gardens. On New England Tableland (NE New South Wales), occupied extensive eucalypt woodland away from streambed and dominated by Blakely's red gum (*Eucalyptus blakelyi*), and with increasing abundance of yellow box (*Eucalyptus melliodora*) with distance from stream, in preference to riverine woodland dominated by river sheoak (*Casuarina cunninghamiana*) or ecotone between eucalypt and riverine woodland mainly of Blakely's red gum and rough-barked apple (*Angophora floribunda*). During autumn and winter often in heathland or coastal woodland with heath understorey, particularly heathland dominated by *Banksia*. Rarely recorded in low closed forest or dry monsoon forest.

Food and Feeding. Mainly arthropods (insects, some spiders), honeydew (including of Eriococcidae) and lerp (of Psyllidae); also nectar, mainly from eucalypts but also other species, including mistletoes (Loranthaceae); occasionally fruit. At one site in Victoria, insects and their products (lerp, honeydew) and nectar comprised roughly equal proportions of diet, but birds fed predominantly on nectar in summer, and more on honeydew and lerp during autumn–winter; on New England Tableland, mainly insects and less often nectar. Forages at all heights, mainly in crowns of trees, less often in understorey; mainly among foliage and at flowers of trees or shrubs (overwhelmingly eucalypts, some in mistletoes or other trees or shrubs, such as *Acacia*), also on bark of twigs and large and small branches, on trunks of trees, in air, and occasionally on ground among grass and litter. Nectar obtained by directly probing flowers; insects caught mainly by gleaning, but also by probing under bark or, less often, by sallying, including sally-strikes on foliage and in air, sally-hovering and sally-pouncing. On New England Tableland, mean proportion of daytime spent in foraging 60% over whole year, but greater during autumn–winter (60–80%) than in spring–summer (45–50%). In C Victoria, diurnal foraging characterized by early-morning phase with high levels of nectar-feeding and low levels of insect-eating, and rest of day with increased levels of insect consumption. Gregarious, often in small active flocks to 20 or more individuals, and considered semi-colonial; can occur in larger flocks, of up to 150, on passage. Often associates with other bird species; also in mixed flocks in non-breeding season. On New England Tableland, foraged at similar heights and mainly among foliage whether *L. penicillatus* present or not, but more on trunks of trees and less at flowers in areas where *L. penicillatus* absent; choice of foraging trees and foraging methods not affected by presence or absence of latter species.

Breeding. May–Mar, mainly late winter to late summer, with clutches recorded Jul–Feb; at Armidale (NE New South Wales) season starts later and ends earlier, late Aug to early Feb (most activity Oct–Nov), with up to five breeding attempts, typically 3–4, of which two may be successful. Nest built usually by female alone, occasionally assisted by male, a well-built cup (though some purse-like or rounded) of fine grass, spider web, bark and wool or hair (which can be taken from live animals), bound with spider web or wool, lined with grass, wool or fur and plant down, sometimes unlined or sparsely lined (other materials include spider egg sacs, plant down or fibre, cotton, twigs, rootlets and moss and lichen), external diameter 4.8–7 cm, depth 5.1–7.6 cm, internal diameter 3.9–4.3 cm, depth 2.9–4.4 cm; suspended in outer foliage or between twigs among dense foliage at end of branch, mainly in crown of eucalypt or tall acacia, occasionally in mistletoe, 0.15–2.5 m (mean 4.9 m) above ground, at Armidale usually suspended from leafy horizontal or vertical twigs 0.8–3.0 m (mean 1.4 m) up. Clutch 1–3 eggs, once 4, mean throughout range 2.4 eggs; incubation, brooding and nest maintenance by female only, most brooding during first 5–6 days; chicks fed by both parents, mostly by female in first two-thirds of nestling period, and then more equally by sexes; at Armidale, incubation period 11–18 days (average 14.9 days), nestling period 12–19 days (average 15.7 days); fledglings fed by both parents, probably independent 4–6 weeks after leaving nest, although later broods may remain with parents for up to 2 months. Nests parasitized by Horsfield's Bronze-cuckoo (*Chrysococcyx basalis*) and Pallid Cuckoo (*Cuculus pallidus*). For 55 eggs in 27 nests throughout range, 0.33 fledged young per nest; of 64 nests where outcome known, 34.4% fledged at least one young; at Armidale, overall success of 127 nests 28.2%, but as low as 7.5% in very dry season and as high as 40.9% in very good season, and success significantly higher at sites with high density of present species (where group defence more likely to occur) than at sites with low density.

Movements. Variable. Resident or partly so over much of range, with some local movements. Altitudinal migrant in S Highlands, making post-breeding descent during autumn–winter (e.g. migration to lower altitudes of Australian Capital Territory in Apr) and returning to higher levels late winter (e.g. mid-Aug); few remain in lowlands during summer. Changes in seasonal occurrence or abundance, or movements, observed in some other areas, but extent of movements not known and perhaps largely local; apparent departure or arrival noted in some places, e.g. near Mudgee (C New South Wales) present throughout year but abundance highest Dec–Jun, few present after Jul, before increase again in Dec. Occasionally recorded in unusual numbers or beyond normal range, with some occurrences consistent with timing of more regular movements. Local abundance often associated with availability of food or seasonal conditions. Migratory populations often in small flocks, often with *L. chrysops* and *Melithreptus lunatus*. Nominata race vagrant in SE South Australia.

Status and Conservation. Not globally threatened. Reasonably common or locally common. No estimates of total population; recorded densities of 0.1–5.4 birds/ha. Thought to have declined in coastal SE New South Wales, and no longer occurs SW Sydney.

44. Yellow-tinted Honeyeater

Lichenostomus flavescens

French: Méliophage flavescens **German:** Sichelohr-Honigfresser **Spanish:** Mielero Amarillento
Other common names: Pale-yellow/Yellowish Honeyeater

Taxonomy. *Ptilotis flavescens* Gould, 1840, Derby, King Sound, Western Australia.

Forms a superspecies with *L. fuscus*, with which formerly often considered conspecific; both are part of a species group that includes also *L. ornatus*, *L. plumulus* and *L. penicillatus*. New Guinea birds very similar in appearance to Australian ones, but treated by some authors as a separate race, *germanus* (described from Laloki R. in Port Moresby District); further study required. Proposed races *deserticola* (from Margaret R. in Kimberley District of Western Australia) and *zanda* (from Normanton, Gulf of Carpentaria, in Queensland) are synonyms of nominate. Two subspecies recognized.

Subspecies and Distribution.

L. f. melvillensis (Mathews, 1912) – Tiwi Is (Bathurst I, Melville I), off N Northern Territory, in N Australia. *L. f. flavescens* (Gould, 1840) – SE New Guinea (from Aroa R E to near Port Moresby, inland to Sogeri Plateau); and from N Western Australia (Kimberley Division and associated offshore islands) E through S Port End (largely absent Arufura coast and most of Arnhem Land) to N & NW Queensland.

Descriptive notes. 13–15.5 cm; male 11–16 g and female 9.5–15.5 g (nominate), male 16.5–17 g and female 13–15.5 g (*melvillensis*). Nominant race is mostly light grey-brown above, with yellow-olive forehead and lores merging into olive-grey crown and nape, yellow tinge on uppertail-coverts, strong yellow-olive panel on folded wing (formed by outer edges of remiges); tail with yellow-olive sides and (in fresh plumage) white tip; side of head and most of underbody yellow, bold black crescent across lower and rear ear-coverts (narrow below front of eye and broadening to rear), bordered below and behind by a diffuse bright yellow

plume; diffuse and often faint grey-brown streaking on breast, side of belly and flanks; undertail-coverts off-white, undertail brownish-grey; underwing off-white with brownish-grey trailing edge and tip; iris dark brown to grey-brown; bill and gape black; legs pinkish-brown or pinkish-grey. Sexes alike in plumage, male slightly larger than female. Juvenile is duller and paler than adult, with paler yellow sides of head and upper neck, dark crescent duller and less conspicuous, narrow olive tip of tail and, most obviously, brown bill with black tip and yellow-orange cutting edges, and swollen yellow gape. Race *melvillensis* is similar to nominate, but with significantly longer bill, slightly darker, more olive-brown, upperbody, stronger olive tone on forehead, lores and crown, and more strongly yellow and more heavily streaked breast, belly and flanks. **Voice.** In Australia, song “porra-cheu, porra-cheu, porra-cheu-cheu”, described as short series of calls; in New Guinea, brief bubbling series of short notes. Song given in flight, in synchronized duets between pair-members, and in agonistic interactions. Contact call a harsh descending “tew” or “taw”; in Australia alarm a rather weak trilled “weeweeeweeewee”, in New Guinea repeated high “wi wi wi...” of 12 or more notes. Other calls reported in New Guinea include hard but rich, rapid, churring and slightly descending “trrrrrrr”, 0.7–1.3 seconds, by two or more birds, probably in threat, and sometimes repeated; short sharp “chip” or “chop”, fairly high-pitched; low-pitched, harsh scolding notes, often between members of group when harassing other species; thin contact note, “tsip”; short downslurred trill of c. 4 notes, repeated over and over and answered by others nearby, given only at dawn, dusk or when sky darkens. Other calls reported in Australia include snake-like hiss, as threat; “eh” note while flying around crocodile; and call sounding like twanging of a short string.

Habitat. Tropical open sclerophyll forests and woodlands, usually near rivers or other wetlands, typically riparian associations dominated by eucalypts, e.g. river red gum (*Eucalyptus camaldulensis*), Darwin woollybutt (*Eucalyptus miniata*), Darwin stringybark (*Eucalyptus tetrodonta*) and bloodwoods (*Corymbia*), paperbarks (particularly *Melaleuca leucadendra*) and *Pandanus*; also in other open or savanna eucalypt forests and woodlands, and open acacia woodlands. Sometimes in grassland with scattered trees, in vine scrubs and thickets, in mangroves (mostly on landward side), and in gardens and parks in towns or around homesteads. In New Guinea, in eucalypt savanna, isolated eucalypts in agricultural land, and in town gardens with eucalypts; in lowlands and foothills, to 450 m.

Food and feeding. Nectar and invertebrates (mostly insects, some spiders), also some seeds (possibly from fruit) and honeydew. Forages at all heights. Insects gleaned from foliage, branches and trunks, occasionally on ground, and caught in aerial sally; nectar taken directly from flowers. In New Guinea, seen to probe fallen flowers on ground. Active and acrobatic; in New Guinea, often hangs upside-down when feeding from flowers. Usually singly, in twos (probably pairs) or in small parties, and said to forage in small flocks of up to 6–8 individuals; small flocks seen to sally for flying termites (Isoptera) above termite mounds. Often indulges in mutual chasing, sometimes ending in fights; aggressive also towards other species. Once seen in mixed-species flock of 40–50 honeyeaters, of six genera, in Australia. Flocks of 20–40 birds seen to drink from pools or water troughs.

Breeding. In Australia recorded in all months, mainly in dry season, but around Innisfail (NE Queensland) said to breed Sept–Oct and Jan, and on Fitzroy R (Western Australia) only in dry season; in New Guinea Mar–May and late Jul to Dec, mostly Sept–Nov. Nest built by female, accompanied by male, a small neat cup typically of fine grass, spider web, plant down, strips of bark and bark fibre, less often moss, rootlets, caterpillar silk and spider egg sacs, firmly woven together, bound with spider web, lined with feathers, fine grass, rootlets or bark fibre, sometimes unlined, external diameter 5.7–6.4 cm, depth 3.3–7.6 cm, internal diameter 4.1–5 cm, depth 3.3–3.6 cm (external length × width for four nests 4.3–6.1 × 3.6–5.3 cm); suspended in cluster of foliage, between branches or in horizontal fork in outer crown of tree (often *Eucalyptus* or *Acacia*), less often closer to trunk, occasionally in mistletoe (Loranthaceae), 13 nests 0.9–1.2 m (mean 6.2 m) above ground. Clutch 1–2 eggs (mean 1.59); incubation period said to be c. 10–12 days; both parents feed chicks, nestling period reported as c. 14 days. Nests parasitized by Brush (*Cacomantis variolosus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*), possibly also by Common Koel (*Eudynamis scolopacea*). Of five nests, four fledged at least one young.

Movements. Resident, recorded throughout year at many sites; some local movements in response to availability of food. Apparently regular summer visitor to Mt Isa (formerly resident), in NW Queensland, from farther N; also vagrant or irregular at sites on periphery of core range. Scattered records farther S in Western Australia, S & N of main range in Northern Territory, and farther N & E in Queensland. Rare records in N Northern Territory (Melville Bay, Gove Peninsula and Darwin) probably involve race *melvillensis*. Once seen as component of a mobile mixed flock of hundreds or thousands of birds.

Status and Conservation. Not globally threatened. Fairly common. No estimates of total population; in Australia, recorded mean density of 0.55 birds/ha NW of Katherine, in Northern Territory. Described as patchily common in New Guinea.

45. White-plumed Honeyeater

Lichenostomus penicillatus

French: Méliophage serti **German:** Weißbüzel-Honigfresser **Spanish:** Mielero Empenachado
Other common names: Carter’s/Cloncurry/Pallid Honeyeater

Taxonomy. *Meliphaga penicillata* Gould, 1837, interior of New South Wales = Wagga Wagga area, Australia.

Forms a species group with *L. ornatus*, *L. plumulus*, *L. fuscus* and *L. flavescens*. Races intergrade where they meet. Described races *centralis* (from C Australia) and *interioris* (Ward R, S of Charleville, in SW Queensland) represent intergrading populations; other proposed races are *geraldtonensis* (from Geraldton, in Western Australia) and *ladasi* (East Murchison, in Western Australia), both merged with *carteri*, and *mellori* (Templestowe, in Victoria), synonymized with nominate. Four subspecies recognized.

Subspecies and Distribution.

L. p. calconii (Mathews, 1912) – extreme SW & S Kimberley (S Fitzroy River Drainage Basin) and adjacent Great Sandy Desert, in N Western Australia.

L. p. carteri (A. J. Campbell, 1899) – Pilbara and Gascoyne regions of Western Australia (from upper De Grey–Fortescue rivers S to Geraldton and N Wheatbelt) E to E Gibson Desert and in Great Victoria Desert to NW South Australia.

L. p. leilavalensis (North, 1899) – NC Northern Territory (from c. 18° S) and NC Queensland S to South Australia (S to Gawler Ranges and N Flinders Ranges) and NW New South Wales (Barrier Range), but largely absent from Simpson Desert.

L. p. penicillatus (Gould, 1837) – Greater Murray–Darling Basin, from CE Queensland (W of Great Divide) S to gulfs of South Australia, extending E to Great Divide and locally to coastal and subcoastal S & SE Australia.

Descriptive notes. 13.5–18 cm; male 17–25 g and female 14–20 g (nominate), male 14.3–20.5 g and female 12–20 g (*leilavalensis*), male 17–19.5 g and female 14.5–17 g (*carteri*), male 16.5–18 g and female 15–18.5 g (*calconii*). Nominant race breeding has largely yellow-olive head, tinged dull olive on top and on chin and throat, with slightly brighter yellow eyering, and conspicuous white neck-plume from side of throat to near nape and edged at front with short black stripe across tips of rear ear-coverts; upperparts mostly greyish-olive, yellow tinge on uppertail-coverts; upperwing mostly brown, with olive to yellow-olive tips

or edges on wing-coverts and yellowish outer edges on secondaries and primaries (form distinct broad panel); uppertail olive-brown with broad yellow-olive sides and, in fresh plumage, white tip; underbody pale brownish-grey, streaked pale yellow in centre of breast and suffused with pale yellow elsewhere, except for cream central lower belly; underwing off-white with broad brownish-grey trailing edge and tip, undertail brownish-grey; iris black-brown to olive-brown; bill and gape black; legs pinkish-grey to purple-grey. Non-breeding plumage as breeding, but has orange-yellow, orange-brown or pink-brown base of bill or base of lower mandible only, and yellow gape. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but top of head and neck duller and greyer, underbody slightly browner, lores, eyering and ear-coverts brighter yellow, white plume smaller and less distinct, little or no black on rear ear-coverts, bill pink or yellowish with brown tip, becoming black with yellow-orange or pinkish base, and gape swollen and yellow. Races differ mainly in size and in intensity of yellow in plumage, nominate race largest: *leilavalensis* is similar in size to nominate (but with shorter wing and tail), also paler and yellower above and on chin and throat, breast paler and less grey, underwing-coverts tinged yellow; *carteri* is smaller than nominate, similar to previous but with shorter tarsus, yellower above and below, brighter yellow on face and underwing-coverts; *calconii* is similar in size to *leilavalensis* but with plumage yellower, and is paler yellow than preceding race. **Voice.** Three main songs and a range of calls. Main song “chick-o-wee” or “chick-oo-wee” or “chick-ick-o-wee” or “cheep a cheep” and many variants, duration 0.4–2 seconds; appears to vary geographically, and local populations have more than one song type, e.g. at Clayton (Victoria) three types with variants, and near Adelaide (South Australia) two songs, both of which also varied. Flight song a liquid, rolling warble, consisting of regular series of 3-note phrases. Early-morning song geographically variable; at one site typically a short note (c. 0.1 second) followed by two 4-note phrases (each c. 0.4 seconds), interval between single note and first phrase c. 0.5 seconds and between first and second phrases c. 0.2 seconds, uttered at intervals of 5–10 seconds for up to 18 minutes. Main call a sharp, descending “chip”, often repeated monotonously at intervals of c. 0.5 seconds for up to one minute. Three types of alarm call (intermediate variants common): Type A rapidly repeated sharp, shrill, penetrating “pee-pee-pee...” lasting up to 10 seconds, in response to flying predator; Type B longer notes than previous, slightly harsh, typically in sequence that develops into Type A calls, given when mobbing (or alternating with Type A when mobbing); Type C alarm quite harsh and generally quieter than other two types, usually single or sometimes paired notes (and sometimes in sequence that develops into Type B calls and then into Type A calls), given when disturbed, excited, in aggression or when threatened or alarmed, including as response to predator. Other calls include twittering during corroborees

(see page 534); high-pitched clear tones and ascending whistles during foraging and from high perches; soft “chick, chick” when coming to feed nestlings. Said to mimic Pacific Baza (*Aviceda subcristata*) and Golden Whistler (*Pachycephala pectoralis*). Snaps bill in aggressive interactions. **Habitat.** Dry, open sclerophyll forests and woodlands, typically riparian associations dominated by eucalypts and bordering wetlands such as watercourses, swamps, waterholes, bores and springs; strongly associated with riparian river red gum (*Eucalyptus camaldulensis*) forests and woodlands along watercourses, but occupies wide range of other riparian eucalypt associations, e.g. those dominated by coolibah (*Eucalyptus coolabah*), snappy gum (*Eucalyptus brevifolia*) or bloodwoods (*Corymbia*) or, less often, woodlands and forests dominated by paperbarks (*Melaleuca*) or casuarinas, sometimes co-dominant with eucalypts. Sometimes in other open forests and woodlands dominated by eucalypts, *Acacia*, cypress-pines (*Callitris*) or casuarina, or occasionally combinations of these, though rarely in mallee eucalypt associations. Often in remnants or isolated trees in cleared lands or built-up areas, or in shelter-belts or plantations of eucalypts; commonly in parks and gardens in cities and towns and around homesteads.

Food and Feeding. Mainly nectar, arthropods, and manna; also pollen and fruit and, very occasionally, seeds (most probably ingested with fruit); seen to take a small skink (Scincidae). Arthropods mainly insects, but also spiders (Araneae), pseudoscorpions (Pseudoscorpiones) and, rarely, snails (Gastropoda); insect products including honeydew (of Ericococcidae, Pseudococcidae and Psyllidae) and lerp (produced by psyllids). In one study, ratio of nectar to insects in diet 31:69; at another site, fed mainly on manna from foliage of manna gum (*Eucalyptus viminalis*) throughout year, also on nectar, mostly in spring. Forages at all levels, from canopy to ground, mainly in tree crowns and less often in saplings or shrubs, only occasionally in air or on ground; on New England Tableland (NE New South Wales), mainly 5–13 m above ground but used wide range of heights. Nectar usually taken by directly probing flowers, especially of eucalypts, but often mistletoes (of genera *Amyema*, *Lysiana*); sometimes steals nectar from tubular flowers (e.g. *Tecoma*, *Correa*, *Lachenalia*) by piercing base of flower or slitting flower from tip to base. Insects, insect products and manna mainly gleaned from foliage, bark and, sometimes, ground; also probes beneath loose bark, and captures insects by sallying. Vocal, bold and very active. Singly, in twos (probably pairs) and in small flocks of 5–7 individuals (or up to 20 when drinking); gregarious and possibly colonial or semi-colonial, with much social interaction within groups; at one site, appeared to occur in groups of c. 12 in non-breeding season but in smaller groups, perhaps solitary pairs, in breeding season. On New England Tableland, foraging behaviour influenced by presence of *L. fuscus*: where co-occurred with latter, present species usually foraged at lower levels, and less often in foliage and more on trunks of trees and in air, than it did in areas without *L. fuscus*; no difference in foraging method or tree species used, whether congener present or not, but tended to select different tree species regardless.

Breeding. Recorded in all months, most clutches (72%) in late Aug to Nov; usually two and sometimes three clutches in a year. Nest probably built by female only, a small, neat, fragile and slightly swollen cup, usually of woven grass, bound with spider web or wool, sometimes with hair, plant or synthetic fibres, plant down, feathers, bark strips or fibres, fine twigs, egg sacs, rootlets, leaves, flowers, moss, lichen or plastic, lined with wool, hair, feathers, fine grasses or, less often, plant down, fur or rootlets (parts of nest plant can be incorporated), external diameter 5.1–8.9 cm, depth 5.1–6.4 cm, internal diameter 5.7 cm, depth 3.8–4.4 cm; typically suspended 0.4–3.3 m (mean 3.7 m) above ground in crown of tree, especially eucalypt, less often in shrub, vines or very occasionally mistletoes or artificial site, in foliage, less often in twigs or fork, and occasionally in dead foliage of fallen limb or tree. Clutch 2–3 eggs, occasionally 1 and rarely 4, mean 2.31; incubation probably by female only, period 13–15 days; chicks fed by both parents, nestling period 11–15 days; juveniles fed for at least 2 weeks after fledging, by both parents, occasionally assisted by auxiliaries. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*) and Horsfield’s (*Chrysococcyx basalidis*) and Shining Bronze-cuckoos (*Chrysococcyx lucidus*). From 177 eggs in 82 complete clutches, 0.6 fledged young per nest; of 240 nests where outcome known, 64.6% fledged at least one young.

Movements. Breeding adults resident, but some local movements, e.g. at Mt Isa (NW Queensland), small proportion of population makes short movements during wet season, and in SE leaves suburban gardens of Canberra in spring, probably moving to nearby reserves to breed. Subadults may disperse widely from natal area. Some movements evidently associated with availability of water, e.g. short-distance shifts away from permanent water during wet season, and to more suitable habitat during severe droughts; can appear at water sources remote from permanent wetlands. Vagrant or sporadic at sites at periphery of range, e.g. occasional records (probably of race *leilavalensis*) N of 18° S in Northern Territory, and in Western Australia *carteri* vagrant near Perth and Kellerberrin.

Status and Conservation. Not globally threatened. Widespread and locally common; sparsely distributed in some areas, e.g. NW part of South Australia, and largely absent from Simpson Desert, in C Australia. Recorded densities of up to 14.3 birds/ha. Range has changed in several regions: increases in range and abundance in e.g. Sydney and Newcastle (New South Wales), and range contractions in e.g. Illawarra region (New South Wales) and Wilsons Promontory (Victoria). Readily adapts to urban habitats, and one of the commonest honeyeaters of urban Australia. At least formerly, occasionally responsible for damage to soft fruits in orchards.

Genus *PURNELLA* Mathews, 1914

46. White-fronted Honeyeater

Purnella albifrons

French: Méléphage à front blanc **German:** Weißstirn-Honigfresser **Spanish:** Mielero Frentiblanco

Taxonomy. *Glyciphila albifrons* Gould, 1841, York District, south Western Australia.

Genus sometimes merged with *Phylidonyris*. Species has in the past been placed with *Phylidonyris novaehollandiae* and *Phylidonyris niger* in a separate genus, *Meliornis*; has also been thought to be close to *Glyciphila melanops*. Monotypic.

Distribution. Widespread through arid and semi-arid Western Australia E to S Northern Territory (mostly S of 23° S), SW Queensland (S from about Mt Isa), South Australia (mostly N of 33° S), W New South Wales and W Victoria (in Mallee and Wimmera regions, mainly N of 37° S).

Descriptive notes. 13–18.5 cm; male 15–22 g, female 12–19 g. Plumage is mostly black-brown above, with fine white scaling on crown and nape merging into heavy white streaking on hindneck and most of upperbody, and with pale rufous streaking on dark brown rump; side of long sloping forehead, lores, eyering and submoustachial stripe white, dissected by thin black-brown moustachial stripe; ear-coverts silvery grey, merging into uneven white stripe extending broadly down side of neck; upperwing dark brown, white to yellow-olive margins on wing-coverts and tertials, yellow-olive edges on rest of remiges (broad panel on folded wing); uppertail dark brown with fine yellow-olive edges and white tip; bold black-brown bib from chin to upper breast (in fresh plumage chin and throat sparsely and finely speckled white), this merging to white with diffuse black streaking on flanks, and white on rest of underbody; undertail brownish-grey, underwing pale orange-buff with brownish-grey trailing edge and tip; iris reddish-brown, small area of bare pink-red skin behind eye; bill and gape black; legs grey-black. Sexes alike in plumage, male larger than female. Juvenile is paler than adult and without bold facial markings, has forehead, lores and submoustachial stripe greyish-brown and contrasting little with dark brown of rest of head and neck, but with white stripe on side of neck (as adult), paler and browner upperside, brown upper breast, gape cream or yellow and swollen, iris brown, bare patch behind eye smaller and less intensely coloured. Voice. Can be noisy when nesting. Main call a distinctive, ringing, metallic “tink-tink”, “chink-chink”, “cheep-cheep” or “chip-chip”. Song described as “pert-peatoo-weet” or “peter-peat-peat”, first note rather harsh, rest more musical. Alarm is a scolding “tuck, tuck” with a click. Other calls include a peevish, grating “tweet”, a gravelly or metallic “kweet” or “kwaak”, and a mournful and long-drawn “cre-e-e-k”; also utters “chu-chu-chu”, occasional trill, mellow “tok-tok” (may be same as “tink-tink”), and flat, short, nasal “wha-wha”. Reported to mimic Australian ringnecks (*Barnardius*) and Crested Bellbird (*Oreocitta gutturalis*).

Habitat. Occupies fairly dense mallee eucalypt shrubland, woodland or heathland, with shrub layer often dominated by *Acacia*, *Eremophila* or broombush (*Melaleuca uncinata*), and ground cover of bluebush (*Maireana*) or spinifex (*Triodia*); these include dense regenerating patches of burnt or harvested mallee eucalypts or broombush. Also, often found in *Acacia* shrublands, usually with ground cover of chenopods or grasses. Sometimes in non-mallee eucalypt woodlands, including riparian woodlands dominated by river red gum (*Eucalyptus camaldulensis*), and sometimes mixed with other species such as cypress-pine (*Callitris*) and *Banksia*; also occurs in non-eucalypt associations, including casuarina shrublands and woodlands, cypress-pine woodlands, *Banksia* woodlands, and riparian paperbark (*Melaleuca*) associations. Inhabits arid and semi-arid zones, sometimes coastally.

Food and Feeding. Diet consists mainly of nectar, e.g. of *Eucalyptus*, *Erythrina*, *Lophostemon*, *Eremophila*; also arthropods (mostly insects, some spiders), occasionally honeydew. Forages in trees (particularly *Eucalyptus*), shrubs (including *Banksia*, *Epaeris*, occasionally broombush) and mistletoes (e.g. of genera *Amyema*, *Lysiana*), mainly at flowers but also in foliage, on branches; occasionally on ground or aerially. Probes flowers for nectar; takes insects by gleaning and sallying. When taking nectar from the mistletoe *Amyema linophyllum*, moves rapidly from one inflorescence to another. Wary and gregarious; often in twos (probably pairs) or small loose parties, and in large numbers in areas with abundant flowering plants; sometimes singly. Often forages with other meliphagids.

Breeding. Season Aug–Nov, but occasional records for all other months (mostly Feb–Jul); probably double-brooded. Possibly semi-colonial breeder, often many nests in small area. Nest built by female, cup-shaped, usually of woven grass, bark, twigs, plant stems and spider web, lined with plant down, wool or fur and, less often, fine grass, woolly seeds and other soft material, sometimes unlined, external diameter 6.2–8 cm, depth 5.7–6.4 cm, internal diameter 3.8–5.1 cm, depth 3.8–5.5 cm; usually supported, sometimes suspended by rim, 0.2–4.55 m (mean 0.94 m) above ground in small shrub, less often in tree (often *Eucalyptus*), occasionally in top of clump of spinifex, atop stump or broken trunk, or in mistletoe. Clutch 1–3 eggs, usually 2 (mean 2.09); incubation begins when clutch complete, probably by female alone, period usually 13 days, once 12 days; chicks fed by both sexes, nestling period 10–12 days; both sexes feed fledglings. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*) and Horsfield’s Bronze-cuckoo (*Chrysococcyx basalidis*). From 128 eggs in 65 nests, 0.86 young fledged per nest.

Movements. Complex, not fully understood; described as resident at a few sites. Generally highly mobile, but extent and patterns of movements not known. Irregular visitor in many areas; occasional influxes or irruptions, especially at edges of range. At many sites occurrence seasonal and species thus sometimes considered migratory; movements in some areas may exhibit regular seasonality if flowering regime constant. Often travels in parties, occasionally in hundreds or thousands, and recorded rates of up to 50–60 birds per minute on passage. Vagrant Kangaroo I (South Australia), and E & S of normal range in E Australia, especially during extreme conditions (e.g. prolonged droughts).

Status and Conservation. Not globally threatened. Locally common. No estimates of total population; recorded densities of up to 0.73 birds/ha. Widespread, but largely absent from SW and far N of Western Australia, and scattered in Western Australian deserts and Simpson Desert; in South Australia, absent from much of NE, and from S Eyre and Yorke and Fleurieu Peninsulas, Adelaide Plain and SE.

Genus *MELIDECTES* P. L. Sclater, 1874

47. Bismarck Honeyeater

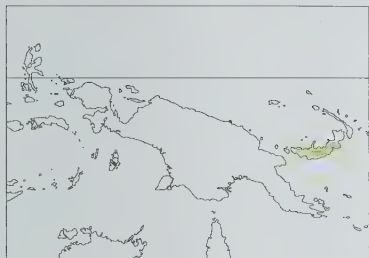

Melidectes whitemanensis

French: Méléphage de Whiteman **German:** Gilliardhonigfresser **Spanish:** Mielero de las Bismarck
Other common names: Bismarck/Gilliard's/Vose's/Whiteman (Mountain) Melidectes, New Britain/Gilliard's Honeyeater

Taxonomy. *Vosea whitemanensis* Gilliard, 1960, Wild Dog Range, Whiteman Mountains, central New Britain, Bismarck Archipelago.

Affinities uncertain, and sometimes placed in a monotypic genus, *Vosea*; further research needed. May be closest to *M. fuscus*. These two, together with *M. nouhuysi* and *M. princeps*, comprise a group of medium-sized species that differ from others in genus in size, morphology, plumage and voice. Monotypic.

Distribution. New Britain (Whiteman Mts, Nakanai Mts and Mt Talawae), in Bismarck Archipelago.

Descriptive notes. 22.5 cm; female 42–49 g. Head and neck are olive-brown, slightly darker on forehead, lores and ear-coverts, with narrow pale grey (faintly yellow-tinged) eyering and area of bare skin below and behind eye, very faint pale speckling on ear-coverts, and faint and fine paler streaking on malar region, chin, throat and side of neck; upperbody olive-brown, blackish-brown scapulars, faint dark olive scalloping on mantle and upper back, and yellowish-brown tinge on lower back to uppertail-coverts; uppertail blackish-brown, yellowish-olive central rectrices and outer edges of rest of rectrices (folded tail appearing

largely yellowish-olive); upperwing blackish-brown, prominent yellowish-olive outer webs of secondaries, yellowish-olive outer edges on all except outer few primaries, and yellowish-olive outer webs and tips of coverts (folded wing appears largely yellowish-olive; spread wing blackish-brown with conspicuous large yellowish-olive patch across remiges); underbody olive-brown with faint, fine pale streaking on upper breast (as chin and throat), merging into slightly paler and yellow-tinged rear flanks, vent and undertail-coverts; undertail dark grey; underwing-coverts dull greyish-brown, tinged yellowish, remiges dull grey; iris dark brown; bill black; legs dark grey. Sexes alike in plumage, female slightly smaller and somewhat duller than male (doubtfully distinguishable in field). Juvenile undescribed. **VOICE.** Song of 3–8 soft, mellow, whistled 2-note syllables (at rate of c. 1.4 syllables per second), first note of each syllable simple, second slightly lower in pitch, trilled or uneven and downslurred (likened to song of *M. fuscus*, but considerably shorter). **Habitat.** Primary montane forest; observed in urban gardens at Keravat. From 900 m to above 1740 m, mainly above 1300 m.

Food and Feeding. Diet includes nectar and arthropods. Forages in middle and upper levels, e.g. seen to probe long red-and-yellow mistletoe flowers (Loranthaceae) c. 8 m above ground in subcanopy. Highly active, moving abruptly and jerkily, staying at a spot for only a few seconds before moving 20–40 cm to another, either hopping along branches or suddenly taking flight. Often acrobatic, hanging vertically with head down, or hanging with body horizontal and head turned downwards, or hanging with body horizontal and twisting head almost 180 degrees to axis of body to reach upwards; grips bark with feet and claws. Also flattens and extends body to peer forwards when searching. Usually singly, occasionally in small numbers in flowering trees; sometimes associates with other species, such as *Philemon cockerelli*.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in New Britain and New Ireland EBA. Generally widespread and common to uncommon; common around Mt Talawae, but uncommon to very uncommon in other parts of range. Considered potentially at risk as it is undergoing very slow decline in area of forest habitat.

Bibliography. Anon. (2007a), Bishop & Jones (2001), Buchanan *et al.* (2008), Coates (1990), Diamond (1971), Dutton (1997a), Gilliard (1960), Gilliard & LeCroy (1967b), Mayr & Diamond (2001), Smith (1991), Stattersfield *et al.* (1998).

48. Sooty Honeyeater

Melidectes fuscus

French: Méléphage fuligineux **German:** Buntwarzen-Honigfresser **Spanish:** Mielero Fuliginoso
Other common names: Sooty Melidectes

Taxonomy. *Acanthochoera fusca* De Vis, 1897, Mount Scratchley, Wharton Range, south-east New Guinea.

Study of relationships within genus needed. Present species sometimes placed with *M. nouhuysi* and *M. princeps* in a separate genus, *Melionyx*; all three, along with *M. whitemanensis*, comprise a group of medium-sized species that differ from others in genus in size, morphology, plumage and voice. Birds in Eastern Highlands proposed as a separate race, *gilliardi* (described from Mt Wilhelm, in Bismarck Range), but intermediate geographically and morphologically between *occidentalis* and nominate, and synonymized with latter. Two subspecies recognized.

Subspecies and Distribution.

M. f. occidentalis Junge, 1939 – Central Ranges of New Guinea, from Snow Mts (Nassau Range and Oranje Mts) E to Eastern Highlands (Mt Hagen, Mt Wilhelm, and Mt Giluwe and Kubor Range). *M. f. fuscus* (De Vis, 1897) – mountains of SE New Guinea E from Eastern Highlands.

Descriptive notes. 21–25.4 cm; 25–42.9 g (nominate). Male nominate race is wholly dark brownish-black above, slightly browner on wings and tail, feathers of upperbody faintly tipped paler, greyish, giving faint mottled or scaled effect (pronounced when plumage fresh, very faint with wear, often

difficult to see in field); small pale blue eye wattle (variable, sometimes pale yellow in centre), extending narrowly in front of and behind eye and dropping below eye, small spot of red to orange-red bare skin behind wattle at rear of eye (note also that face, particularly forehead, can be coloured by pollen from flowers); outer webs of remiges faintly tinged dark red-brown; black-brown to dark brown below, slightly paler than upperparts, paler brown on vent and undertail-coverts, fine pale brown to brownish-grey speckling or fine streaking on chin and throat merging into pale brown crescent-shaped scaling on underparts (except vent); some feath-

ers of breast and belly faintly tinged rufous-brown in centre; undertail black-brown, with paler, light grey-brown tips on outer feathers (lost or almost lost with wear); shafts of remiges and rectrices dark red-brown; iris dark brown (described as green on one museum label); bill black; legs blue-grey. Female is like male but smaller; suggestion that female has slightly greyer tinge on belly and smaller wattle requires confirmation. Juvenile is duller than adult, brownish-black, with little or no pale tipping on feathers of upperparts, underbody more mottled and less scaled, mottling greyer, undertail-coverts richer brown; bill probably shorter and gape yellow at first, eye wattle and skin behind eye both pale yellow, legs bluish-pink. Race *occidentalis* is very like nominate, but smaller. **VOICE.** Call a pair of rather soft, upslurred notes, “schweep-schweep”. Two song types described (possibly varying geographically): one a long and monotonous repetition of high-pitched 2-note phrase, second note trilled or slurred and lower than first, at rate of 90 phrases per minute for up to a minute or more (likened to song of *M. whitemanensis*, although repeated far more times); second type a sweet, airy, high-pitched series of whistles gradually dropping in pitch and then continuing on single pitch, “see-dee-dee-dee-dee-dee...”. Independent fledgling continually uttered “pzeep” note.

Habitat. Primary upper montane forest and high mountain forests (particularly moss forest), forest edge, secondary growth, and alpine shrubland and shrub thickets within or at edge of grassland; on Mt Albert Edward, recorded in dense secondary growth at edge of moss forest damaged by fire; in dense secondary growth in clearings in mossy beech (*Nothofagus*) forest at low altitude at Ok Tedi; at Tari Gap, observed and netted mainly in forest patches bordering grassland. On Mt Wilhelm recorded as breeding in old landslip area surrounded by forest. From 2200 m to tree-line at c. 3720 m, mainly in alpine zone above 3000 m; exceptionally down to c. 1700 m in Ok Tedi area. Recorded at 3050–3350 m on mounts Hagen, Wilhelm, Giluwe and Kubor, and breeding at 3460 m on Mt Wilhelm; at 2740–3300 m on Mt Albert Edward, 3200 m at Dokfuma (Star Mts). Co-exists with *M. belfordi* in SE New Guinea, with *M. princeps* in Eastern Highlands, and with *M. nouhuysi* on S slopes of Snow Mts. **Food and Feeding.** Diet includes arthropods (insects), nectar, pollen and fruit (including berries). Forages at all levels, from crown to understorey; often seen in shrubs and low trees in clearings in forest and in alpine shrubs. Gleans arthropods from foliage and weeds, probes flowers (often of *Rhododendron* and *Vaccinium*, also *Dimorphanthera*); seen to probe for pollen in mature male cones in crowns of *Dacrycarpus compactus*. Active, darting rapidly among twigs and foliage, and hopping along branches; often holds tail cocked. Almost always singly, occasionally in twos (possibly pairs); does not congregate in flowering trees. Described as unwary to quite tame, but very shy at Ok Tedi.

Breeding. Nest with egg in Oct, nestlings early Oct, early Nov and May, nests reported also in Apr (two) and Jun (five), and dependent fledglings in Jul; possibly bimodal, breeding at end of wet season and start of dry season and also in late dry season. Nest a bulky, deep, thick-walled cup, one made of moss and some fine grass and lined with dark feathers, another of fine rootlets and covered externally with moss and lined with tree-fern fibres, external diameter 17.5 cm, depth 19 cm, internal diameter 7.2 cm, depth 4.3 cm; placed in upright fork and usually not far from ground, one c. 3 m up in fork of *Rhododendron*, another 1.9 m up in nearly vertical fork of densely foliated sapling in small patch of shrubs. Clutch (Mt Wilhelm) 1 egg; no information on duration of incubation and nestling periods, at one nest chick fed by both parents; one juvenile fed by adult but also feeding itself c. 2 weeks after fledging, and foraging apparently independently within c. 3 weeks of fledging.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. No estimates of global abundance; generally considered scarce, although locally common to abundant in SE. In English Peaks, in Wharton Range, 53 individuals mist-netted in one month.

Bibliography. Anon. (1994c), Beehler (1978a), Beehler *et al.* (1986), Bell (1969, 1971a), Clapp (1986b), Coates (1990), Coates & Peckover (2001), Coles (1995), De Vis (1897), Diamond (1972a), Filewood (1969), Frith & Frith (1992), Gregory (1995b), Gregory & Johnston (1993), Hicks (1988d), Hicks & Burrows (1989, 1992), Hopkins (1992), Mackay & Martin (1976), Mayr & Gilliard (1954), Mayr & Rand (1937), Ogilvie-Grant (1915), Rand (1936b, 1942b), Rand & Gilliard (1967), Sims (1956), Smith (1976), Stattersfield *et al.* (1998).

49. Short-bearded Honeyeater

Melidectes nouhuysi

French: Méléphage à barbe courte **German:** Kurzbart-Honigfresser **Spanish:** Mielero Barbicorto
Other common names: (Short-)bearded/Nouhuys's Melidectes

Taxonomy. *Melirrhophetes nouhuysi* van Oort, 1910, Oranje Mountains, west-central New Guinea. Study of relationships within genus needed. Forms a superspecies with *M. princeps*, and both species, together with *M. fuscus*, are sometimes placed in a separate genus, *Melionyx*; these three, along with *M. whitemanensis*, comprise a group of medium-sized species that differ from others in genus in size, morphology, plumage and voice. Length of bill may vary, being longer in Star Mts than in Snow Mts; study required. Monotypic.

Distribution. Highest mountains of Central Range in Snow and Star Mts, including Nassau Range, Mt Capella and Dokfuma Meadow, in WC New Guinea.

Descriptive notes. 27–27.5 cm. Appears wholly dark blackish-brown to sooty black, tinged brownish on lower belly, with small patch of yellow to golden-yellow bare skin behind eye; indistinct white tip of tail; white chin and throat (except for black centre of throat), feathers of which slightly elongated and tufted, forming short but prominent “beard” at side of throat (not reaching close to angle of folded wing); varying greyish scalloping on breast, belly and vent, pale buff scalloping on

On following pages: 50. Long-bearded Honeyeater (*Melidectes princeps*); 51. Cinnamon-browed Honeyeater (*Melidectes ochromelas*); 52. Vogelkop Honeyeater (*Melidectes leucostephes*); 53. Belford's Honeyeater (*Melidectes belfordi*); 54. Yellow-browed Honeyeater (*Melidectes rufocrissalis*); 55. Huon Honeyeater (*Melidectes foersteri*); 56. Ornate Honeyeater (*Melidectes torquatus*); 57. San Cristobal Honeyeater (*Meliarchus sclateri*); 58. Bell Miner (*Manorina melanophrys*); 59. Noisy Miner (*Manorina melanocephala*); 60. Black-eared Miner (*Manorina melanotis*); 61. Yellow-throated Miner (*Manorina flavigula*); 62. Spiny-cheeked Honeyeater (*Acanthagenys rufogularis*).

undertail-coverts; iris dark brown to dark reddish-brown; bill black; legs pale blue-grey, but described also as brownish-black and black. Sexes alike in plumage, male larger than female. Juvenile undescribed; immature differs from adult in dull yellow wash on whitish elongated feathers of chin and throat, mixed with some off-white feathers (some appear to have white feathering much as adult), olive tinge on breast, yellowish and weaker scalloping on underbody, and buff to rufous-buff undertail-coverts. VOICE. In Snow Mts, scolding call a low, buzzy "chsh" repeated rapidly 4–6 times (sounding like call of a much smaller bird), and utters repeated, sweet scolding "sweet" during mutual chasing. In Star Mts, calls include metallic "pwik", and thin "weet-weet" in flight.

Habitat. Open high mountain forest, forest edge and scattered clumps of shrubs and trees bordering or in alpine grassland at tree-line; usually low in fringing vegetation and shrubs. Recorded from 3050 m to 4500 m; 3300–4500 m in Snow Mts, no lower than upper limit of closed forest (which it avoids); 3200 m Dokfuma Meadow, in Star Mts.

Food and Feeding. Fruit, seeds (including of sedges), arthropods (insects) and nectar. Forages mainly in shrubs or on ground in thickets or clumps, also in upper levels of trees; seen to glean from leaf litter. Secretive but not shy; when pursued by observer, hopped rapidly through shrubs, or flew from one clump of shrubs to another. At Dokfuma (Star Mts), chased by smaller but more aggressive *Lichenostomus subfrenatus*, once to canopy.

Breeding. One nest found, on 10th Aug: a loose, bulky cup-shaped structure of moss, liverworts and thread-like fungi, firmer internal cup sparsely lined with grass and fern stems, plant fibre, fern scales and some feathers, latter mainly from Salvadori's Teal (*Anas waigiensis*), external diameter 16 cm, depth 20 cm, internal diameter 7.5 cm, depth 6 cm, reasonably well concealed among multiple forks 1.2 m above ground in rather isolated shrub in open country; contained 1 egg. No other information.

Movements. No information; probably resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. Very poorly known. Considered generally fairly common (though secretive); not uncommon at Dokfuma, in Star Mts.

Bibliography. Anon. (1994c), Beehler *et al.* (1986), Coates & Peckover (2001), Gregory & Johnston (1993), Mayr & Gilliard (1951), Ogilvie-Grant (1915), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Stattersfield *et al.* (1998).

50. Long-bearded Honeyeater

Melidectes princeps

French: Méléphage à barbe longue **German:** Langbart-Honigfresser **Spanish:** Mielero Barbilargo
Other common names: Long-bearded Melidectes

Taxonomy. *Melidectes princeps* Mayr and Gilliard, 1951, Mount Wilhelm, Bismarck Range, east New Guinea.

Study of relationships within genus needed. Forms a superspecies with *M. nouhuysi*, and both species, together with *M. fuscus*, are sometimes placed in a separate genus, *Meltonyx*; these three, along with *M. whitemanensis*, comprise a group of medium-sized species that differ from others in genus in size, morphology, plumage and voice. Monotypic.

Distribution. Mt Giluwe, Mt Hagen, Kubor Range (including Mt Kubor, Mt Kinkain and Mt Orata, and Minj-Nona Divide), Bismarck Range (Mt Wilhelm), Mt Michael and Kratke Ranges, in east-central New Guinea.

Descriptive notes. 26.5–28.8 cm; one female 42 g. Head, neck and upperparts are black-brown, slightly darker on top and side of head, slightly warmer dark olive-brown on rump and uppertail-coverts, and with sparsely feathered small patch beneath eye blackish, finely speckled with white; small patch of bare skin behind eye is orange, with some yellow and pale greenish; uppertail narrowly tipped brownish-grey on outer edges, and remiges finely edged olive-grey (tips and edges lost with wear); chin and throat covered with long, tufted off-white to white feathers, longest on chin and along side of throat, latter forming

long "beard" that reaches almost to angle of folded wing; underbody dark olive-brown, varying scalloped with grey-brown, most noticeably on breast and lower belly, with some light rufous-brown mottling or scalloping on undertail-coverts; undertail dark olive-brown; underwing dark olive-brown, some faint rufous-brown mottling on coverts, and silvery brownish-grey panel across bases of remiges; iris dark brown to dark reddish-brown; bill black; legs pale grey to pale blue-grey. Juvenile not fully described; immature (or possibly juvenile) said to be sooty black above and washed buff below, especially on belly, with beard dull yellowish-white (not white). Voice. No information.

Habitat. High mountain moss forest and woodland, and clumps of shrubs and scrubby forest thickets in alpine grassland, above and below tree-line. Mainly 3000–3800 m, but recorded to 4200 m and extends as low as 2750 m in Kubor Mts; on mounts Kubor, Hagen and Wilhelm mainly above 3050 m, and to at least 3600 m in Kubor Range.

Food and Feeding. No information.

Breeding. Nestling found in late Jul (Mt Hagen) and dependent fledgling mid-Jun (Mt Wilhelm). No other information.

Movements. No indication of any movements; presumed sedentary.

Status and Conservation. VULNERABLE. Restricted-range species: present in Central Papuan Mountains EBA. Very poorly known, and no estimates of global population or trends. Generally described as fairly common within range. Total population thought to be small, confined to a few sites within a small range, and to be declining owing to loss and degradation of its patchy and dissected habitat. The highlands where species occurs have a dense human population; although cultivation stops below altitudinal range in which the species occurs, there may be some habitat degradation from fires, usually started by hunters. No conservation measures known to be under way.

Bibliography. Anon. (2007a), Beehler *et al.* (1986), Butchart & Stattersfield (2004), Coates (1990), Coates & Peckover (2001), Collar *et al.* (1994), Diamond (1972a), Mayr & Gilliard (1951, 1954), Rand & Gilliard (1967), Sims (1956), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

51. Cinnamon-browed Honeyeater

Melidectes ochromelas

French: Méléphage à sourcils roux **German:** Rostohr-Honigfresser **Spanish:** Mielero Cejirrufo
Other common names: Cinnamon-browed/Dark-mantled/Mid-mountain Melidectes, Dark-mantled/Mid-mountain Honeyeater

Taxonomy. *Melirrhophetes ochromelas* A. B. Meyer, 1874, Hatam, Arfak Mountains, Vogelkop, north-west New Guinea.

Study of relationships within genus needed. Present species and *M. leucostephes*, *M. belfordi*, *M. rufocrissalis*, *M. foersteri* and *M. torquatus* comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Birds in Weyland Mts intermediate between nominate race and *batesi*, and currently included within latter. Three subspecies recognized.

Subspecies and Distribution.

M. o. ochromelas (A. B. Meyer, 1874) – mountains of Vogelkop (Tamrau Mts, Arfak Mts) and Wandammen Mts, in NW New Guinea.

M. o. batesi (Sharpe, 1886) – Weyland Mts, S slopes of Nassau Mts and mountains of SE New Guinea.

M. o. lucifer Mayr, 1931 – mountains of Huon Peninsula, in NE New Guinea.

Descriptive notes. 24–25 cm; male 61.5–65 g, female 54–62.5 g (nominate). Nominate race has top and side of head and chin and upper throat brownish-black, merging into dark brownish-grey or dusky olive-brown with diffuse whitish scaling on hindneck, side of neck and lower throat (combining to form distinct collar); short pale cinnamon supercilium bordering large patch of pale green to greenish-yellow bare skin around eye (very broad behind eye), fine streak of pale cinnamon across rear ear-coverts, grey tinge on lower ear-coverts, merging into brownish-grey side of neck; pale yellowish to yellow gape wattle, small red to

orange-red wattle at side of throat; upperbody dark brownish-grey or dusky olive-brown, heavily scaled pale grey to off-white on mantle, back and scapulars (boldest in mid-line); upperwing and tail brownish-black, broad yellow-olive outer edges on primaries and secondaries (large panel on folded wing), narrow buff tips on outer primaries, and broad greenish-olive outer edges of rectrices (folded tail appears largely yellow-olive with dark centre); underbody brownish-grey or dusky brown, with diffuse pale grey to off-white streaking (or mottling) on breast and belly, merging into broader white barring or mottling on lower belly and vent, and into rufous-buff on undertail-coverts; undertail grey-brown; iris brown to blackish-brown, described also as dark grey; bill pale bluish-grey, paler towards tip; legs pale to dull blue-grey, described also as whitish. Sexes alike in plumage, male larger than female. Juvenile undescribed. Race *batesi* is like nominate but with more pronounced supercilium, and underbody browner and less grey-toned; *lucifer* resembles previous, but darker on head and breast. Voice. Noisy. Vocalizations often comprise 4–5 nasal slurs; also loud, descending "whee oo woo", and bell-like notes like those of Blue Bird-of-paradise (*Paradisaea rudolfi*). Often duets, giving nasal slurs in perfect alternating rhythm.

Habitat. Lower to middle montane forest and forest edge. From c. 1100 m to 1800 m (Huon Peninsula) or 2000 m (SE or range), and locally as low as 770 m; possibly as high as 2590 m on Mt Albert Edward.

Food and Feeding. No details of diet. Usually forages in canopy, subcanopy and middle levels of forest. Pair seen to probe lichen on trees. Noisy and pugnacious. Usually singly, in twos (probably pairs) or in small groups; also congregates in flowering trees with other species, including *Myzomela rosenbergii* and Fairy Lorikeet (*Charmosyna pulchella*).

Breeding. Egg recorded in Jan, and dependent fledgling being fed with insects by both parents in mid-May. Nest undescribed. No other information.

Movements. No information; presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in West Papuan Highlands EBA and in Adelbert and Huon Ranges EBA and in Central Papuan Mountains EBA. Poorly known. Considered generally scarce to rare, but locally common. Unconfirmed report from Ubaigubi, in Eastern Highlands.

Bibliography. Beehler (1978a), Beehler *et al.* (1986), Coates (1990), Diamond (1972b), Draffen (1977), Eastwood & Gregory (1995), Filewood (1969), Finch (1980a), Frith (1971), Hornabrook (1985), Mayr & Rand (1937), Ogilvie-Grant (1915), Peterson (1999), Rand & Gilliard (1967), Stattersfield *et al.* (1998), Stein (1936).

52. Vogelkop Honeyeater

Melidectes leucostephes

French: Méléphage à face blanche **German:** Diademhonigfresser **Spanish:** Mielero de Vogelkop
Other common names: Vogelkop/Arfak/White-fronted Melidectes, Vogelkop Wattled/White-capped/White-fronted(!) Honeyeater

Taxonomy. *Melirrhophetes leucostephes* A. B. Meyer, 1874, Hatam, Arfak Mountains, Vogelkop Peninsula, north-west New Guinea.

Study of relationships within genus needed. Forms a superspecies with *M. belfordi*, *M. rufocrissalis* and *M. foersteri*; all four, along with *M. ochromelas* and *M. torquatus*, comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Sometimes treated as conspecific with *M. belfordi*. Monotypic.

Distribution. Mountains of Vogelkop (Tamrau Mts, Arfak Mts) and Bomberai Peninsula (Fakfak Mts, Kumawa Mts), in NW New Guinea.

Descriptive notes. 26 cm; male 63–97 g, female 65–78 g (Arfak and Tamrau), one female from Kumawa Mts 61 g. Head and neck are black-brown to brownish-black, merging into dark dusky brown with buff mottling on hindneck, and with white forehead; large patch of pale blue-green or pale bluish-white bare skin surrounding eye, broader and tapering to rounded point behind eye, bordered above by white rear supercilium curving over and behind rear edge of orbital patch, and below by white streak from beneath middle of eye and extending back to meet supercilium at rear of bare patch; broad white moustachial stripe continuing to below rear ear-coverts; swollen pinkish gape, and long, broad, fleshy pinkish-red to orange-red or bright red wattle extending from gape well down side of throat; mantle, back and scapulars dark dusky brown, boldly and broadly scaled or scalloped with buff to buff-white, merging to more rufous-brown and unmarked on rump and uppertail-coverts; upperwing and uppertail dark brown, yellow-olive edges on most remiges, narrow whitish tips on all except inner few primaries, and faint olive edges on rectrices; underbody largely black-brown to brownish-black, with broad off-white to buff-white tips at side of breast

and on belly, vent and undertail-coverts (strongly scaled appearance), merging to rufous-brown on vent and to creamy buff to buff on undertail-coverts; underwing pale rufous-buff, mottled with blackish-brown on coverts, and with blackish-brown trailing edge and tip; iris dark brown to black-brown; bill pale bluish-white to pale blue or bluish-grey; legs blue-grey. Sexes alike in plumage, male larger than female. Juvenile not fully known, said to lack wattle. VOICE. In Kumawa Mts, loud calls consist of 2–9 notes, slurs and disyllables, with clear and hoarse notes, screeches, gulps and high nasal notes combined in same call; resemble

loud calls of *M. ochromelas*, *M. belfordi* and *M. rufocrissalis*. Flew with loud wingbeats.

Habitat. Montane forest, and edge of forest bordering grassland. From 900 m to 1800 m; in Kumawa Mts, recorded at 1000–1800 m, possibly down to 850 m; in Fakfak Mts at c. 1200 m.

Food and Feeding. In Kumawa Mts, seen singly, in twos and in threes; probes leaves and flowers, from 5 m above ground to canopy. No other information.

Breeding. No information.

Movements. No information; presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in West Papuan Highlands EBA. Poorly known. Considered generally uncommon in Kumawa Mts.

Bibliography. Beehler *et al.* (1986), Diamond (1985), Eastwood (1966a), Gibbs (1994), Gilliard (1959), Gyldenstolpe (1955b), Mayr & Gilliard (1952a), McCarthy (2006), Peterson (1999), Rand & Gilliard (1967), Stattersfield *et al.* (1998), Stein (1936).

53. Belford's Honeyeater

Melidectes belfordi

French: Méliphage de Belford **German:** Belfordhonigfresser **Spanish:** Mielero de Belford
Other common names: Belford's Melidectes/Black-bill, Arfak White-fronted Honeyeater

Taxonomy. *Melirrhophetes belfordi* De Vis, 1890, Mount Knutsford, south-east New Guinea.

Study of relationships within genus needed. Forms a superspecies with *M. leucostephes*, *M. rufocrissalis* and *M. foersteri*; all four, along with *M. ochromelas* and *M. torquatus*, comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Sometimes treated as conspecific with *M. leucostephes* and with *M. rufocrissalis*. Co-occurs with last-mentioned species on Mt Koimjim (in Schrader Mts), but the two appear to exclude each other altitudinally; the two hybridize freely, however, where they come into contact; Herzog Mts, much of Eastern Highlands, Mt Goliath (in E Star Mts) and N slopes of Snow Mts may once have supported both species, but hybrid populations now found extensively through these areas (although populations of N slopes of Snow Mts are almost pure individuals of present species, with only a few *M. rufocrissalis* characteristics). Race *brassi* and nominate race may represent different species, as they occupy same geographical range but are separated altitudinally and appear not to intergrade; further study needed. Races *joiceyi* and *kinneari* intergrade in W Nassau Mts (Wissel Lakes area). Proposed races *stresemanni* (type from Dawong, in Herzog Mts) and *griseirostris* (type from Mt Goliath, in E Oranje Mts/W Star Mts) represent hybrids. Five subspecies recognized.

Subspecies and Distribution.

M. b. joiceyi (Rothschild, 1921) – Weyland Mts and W Nassau Mts, in W New Guinea.

M. b. kinneari Mayr, 1936 – Snow Mts (including Nassau Mts and Oranje Mts), in W New Guinea.

M. b. schradereensis Gilliard & LeCroy, 1968 – Schrader Mts, in E New Guinea.

M. b. belfordi (De Vis, 1890) – c. 3000 m to c. 3800 m in mountains of SE New Guinea (E from Bismarck–Hagen–Kubor Ranges).

M. b. brassi Mayr & Rand, 1936 – c. 2000 m to c. 2800 m in mountains of SE New Guinea.

small white gape wattle; chin and upper throat black-brown, merging into brownish-grey or pale grey with brownish mottling on lower throat; mantle, back and scapulars black-brown, heavily scaled or mottled grey, merging into dark brown on rump and uppertail-coverts; upperwing and tail black-brown, yellow-olive tips and outer edges on greater coverts, broad yellow-olive outer edges on all except outer two remiges (large yellow-olive panel on folded wing), outer 5–6 primaries also narrowly tipped yellow-brown (reduced with wear), broad yellow-olive outer edges on rectrices (folded tail appears yellow-olive with dark centre); underbody pale grey, mottled dark brown and finely streaked white on breast and belly, merging to broader white barring or mottling on lower belly and vent, which also tinged rufous-brown, and to rufous-brown on undertail-coverts; undertail dark brown; underwing dark brown, slightly paler bases of remiges; iris brown to dark red-brown; bill black to dark greyish-black, sometimes dark-grey lower mandible; legs dark grey to dull blue-grey, varying mottled with brown or brownish-grey, soles yellow. Sexes alike in plumage, male larger than female. Juvenile is like adult but upperbody darker, sooty black-brown, with only faintly paler tips (mottled or scaled effect much reduced), underbody generally darker, blackish-grey, with much-reduced mottling or scaling throughout and a rufous tinge on belly, vent and undertail-coverts, also white malar stripe smaller, less white in line behind eye above rear ear-coverts. Races differ mainly in size and in plumage tones: *brassi* differs from nominate only in smaller size; *kinneari* is smaller than nominate, also paler grey-brown upperparts with paler and olive-tinged scaling on mantle, back and scapulars, brighter more yellowish-green edges of remiges, paler grey underbody with less prominent white markings posteriorly, and bare orbital skin violet-blue, also juvenile bare parts differ from adult's, orbital skin greenish, gape yellow and legs brown (not brownish-grey to dark grey or blackish-brown); *schradereensis* differs from all others in having lemon-yellow (not blue) orbital ring, otherwise like previous in general size and coloration; *joiceyi*

is smaller than others, and with strong olive tinge above. VOICE. Very noisy, its voice an almost ubiquitous sound of higher forests; typically, the first species to call in dawn chorus (starts well before dawn), can be noisy during rainshowers. Vocalizations unmusical and varying; repeated staccato notes and jumbled gurgles or bugling common, but other sounds include repeated hoarse or querulous rasps, coughs and cackles, nasal “caw” notes, and clear, high-pitched piping notes, in alarm also a sharp whistled call, repeated several times. Some calls rendered as loud high “kee kee...”, hoarse “que que...”, loud “whit whit...”, soft “cremm”, loud clear “pip pip...”, and “kee qui qui...”. Duets; on Mt Albert Edward, two individuals faced each other on a branch and uttered “caw” notes rapidly and in perfect alternation up to 34 times.

Habitat. Primary upper montane to high mountain forests, forest edge, secondary growth and disturbed habitats, such as scattered trees in cattle pastures, patches of scrub in cleared areas and remnant forest; at high altitudes, recorded in thickets of shrubs in subalpine grassland. In upper Kaironk Valley, mainly in *Nothofagus* forest. Between Komopa and near Dauwagu, in W New Guinea, recorded also in *Pandanus* scrub and in open scrub with tree-ferns; at Dokfuma, in subalpine herbfield. Mainly above 1600 m, but recorded as low as 1400 m, and ranging up to tree-line in places, to 3800 m in SE, to at least 3350 m in CE and to above 3700 m in Snow Mts, probably up to 4000 m; in W of range, recorded at 3700–4000 m in Carstensz Mts and at 1740 m at Enarotali and 1830 m near Dauwagu; in E, not heard below 2300 m on Mt Koimjim (Schrader Mts) but common in higher forests to summit at c. 2600 m, and common on N side of upper Kaironk Valley from c. 2280 m upwards; on Mt Albert Edward from 2000 m to tree-line (at least 3350 m), but recorded down to 1600 m; in Victor Emanuel Mts at 2200–2300 m; in S foothills and slopes of Wharton Ranges, recorded at 1700–2700 m. Over much of range, replaced at lower altitudes by *M. rufocrissalis* (below 2300 m) or *M. ochromelas*.

Food and Feeding. Diet includes arthropods, mainly insects, including large ants (Formicidae) and beetles (Coleoptera); also nectar, fruit and, probably, pollen. Forages mainly in upper levels of trees, including emergents, and especially in flowering and fruiting trees (e.g. *Banksia dentata*, *Xanthomyrtus papuanus*) or flowering epiphytes (e.g. *Rhododendron*, *Dimorphanthera*); occasionally at ground level, and seen to forage at cluster (4-m diameter) of flowering *Mitrastemma yamamotoi* (a terrestrial root parasite), which birds visited mainly in mornings, usually descending cautiously and probing flowers while gripping vertical stem. Actions rather deliberate. Searches for insects by hopping along branches and up trunks, often head down, probing moss and epiphytes, and gleaning from foliage, vines and, apparently, flowers; often hangs to reach flowers, which it probes systematically. Conspicuous and pugnacious (but race *kinneari* considered surprisingly inconspicuous). Usually seen singly, sometimes in twos (probably pairs). Appears to defend resources from conspecifics and other birds; does not normally congregate in numbers in flowering trees, but may defend parts of trees. Sometimes associates with *Melipotes fumigatus*. Once seen to dive-bomb two Crested Berrypeckers (*Paramythia montium*). When foraging on *Mitrastemma yamamotoi* on ground, present species was found to be the most aggressive of four avian species, and effectively dominated and controlled foraging at the patch in the morning.

Breeding. Apparently predominantly late wet season and dry season: nest-building early Apr, late Jun and late Jul, “breeding birds” May and Aug-Oct, nestlings Apr–May and dependent fledglings early May and late Jun. Nest a deep cup of moss and twigs, densely lined with soft brownish material from base of tree-fern fronds, placed (not known whether suspended or supported) 4.5–9 m above ground in fork of branch in tree, one nest near Dauwagu c. 35 m above ground. No information on clutch size; one reported nest contained one young; both parents observed to feed nestlings and both seen with fledglings. No other information.

Movements. No information; probably largely sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. Common to very common in many parts of range, e.g. upper Kaironk Valley, Mt Koimjim. At English Peaks, at 3650 m in Wharton Range, 22 individuals mist-netted in 17 days. Interbreeding with *M. rufocrissalis* over wide area in E New Guinea; suggested that some hybridization occurs naturally in undisturbed habitats in narrow altitudinal band where the two species overlap, but that large-scale hybridization is a result of extensive habitat disturbance caused initially by indigenous agriculture and possibly other human activities in more recent times. Such habitat disturbance brings the two species into contact over broader areas and permits extensive and accelerated hybridization to take place.

Bibliography. Beehler (1978a, 1994), Beehler *et al.* (1986), Bell (1971a), Clapp (1986b), Coates (1990), Coates & Peckover (2001), Coles, D. (1976b), Coles, T. (1995), Diamond (1967, 1972a, 1972b), Filwood (1969), Frith & Frith (1992), Gilliard (1959), Gilliard & LeCroy (1961, 1968), Gregory & Johnston (1993), Gyldenstolpe (1955a), Heron (1977a), Hicks & Burrows (1992), Hopkins (1992), Iova (1993), Mayr & Gilliard (1952a, 1954), Mayr & Rand (1937), McCarthy (2006), Melville (1979), Ogilvie-Grant (1915), Rand (1936b, 1942b), Rand & Gilliard (1967), Ripley (1964), Rowland (1995), Salomonsen (1967b), Schodde *et al.* (1975), Sims (1956), Stattersfield *et al.* (1998), Tolhurst (1991), Watson *et al.* (1962), Weston (1976a, 1977).

54. Yellow-browed Honeyeater

Melidectes rufocrissalis

French: Méliphage de Reichenow **German:** Reichenowhonigfresser **Spanish:** Mielero Cejamarillo
Other common names: Yellow-browed/Reichenow's Melidectes, Reichenow's Wattlebird

Taxonomy. *Melirrhophetes rufocrissalis* Reichenow, 1915, Schraderberg, Sepik Mountains – Schrader Range, north-east New Guinea.

Study of relationships within genus needed. Forms a superspecies with *M. leucostephes*, *M. belfordi* and *M. foersteri*; all four, along with *M. ochromelas* and *M. torquatus*, comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Sometimes treated as conspecific with *M. belfordi*, and on Mt Koimjim (in Schrader Mts) the two co-occur but appear to exclude each other altitudinally; they hybridize freely, however, where they come into contact; Herzog Mts, much of Eastern Highlands, Mt Goliath (in E Star Mts) and N slopes of Snow Mts may once have supported both species, but hybrid populations now found extensively through these areas (although populations of N slopes of Snow Mts are almost pure *M. belfordi*). Has been suggested that race *thomasi* is of hybrid origin on basis of its black forehead; this race was originally described under name *gilliardi*, but that name invalid, as preoccupied. Precise geographical limits of each race complicated by extensive hybridization with *M. belfordi*. Two subspecies recognized.

Subspecies and Distribution.

M. r. rufocrissalis (Reichenow, 1915) – Central Range of New Guinea, from E Star Mts and Hindenburg Range E to Bismarck Range, Mt Hagen and Kubor Mts.

M. r. thomasi Diamond, 1969 – S slopes of Eastern Highlands from at least Okapa to Mt Karimui and in Morobe Province (in Aseki area).

Descriptive notes. 26–29 cm; male 74–84 g and two females 61 g and 69 g (nominate); male 72.7–96.5 g and female 56–72.7 g (*thomasi*, Mt Karimui), male 70–81 g and three females 58–61 g (*thomasi*, Awande). Nominate race has forehead black, rest of head and neck dusky black-brown, merging into brownish-grey on hindneck, side of neck and lower throat (diffuse, slightly paler half-

collar or collar), with large area of light green to pale greenish-yellow or pale yellow bare skin around eye (narrow in front of and above and below eye, broad behind eye), bordered by small superciliary tuft of bright yellow, and with small yellow streak at rear edge of ear-coverts; long pale yellow to pale greenish-white gape wattle extending across malar area to side of upper throat, bordered below by narrow and wispy whitish submoustachial stripe; small orange-red wattle behind gape wattle on side of lower throat; upperparts dark brown, slightly darker upwing and tail, with broad yellow-olive to olive edges on greater coverts and all

except outer two remiges (on remiges combining to form large panel on folded wing); rectrices also broadly edged yellow-olive (folded tail appears yellow-olive with dark centre); underbody grey-brown, mottled or roughly barred with off-white to light brownish-grey, undertail-coverts rich chestnut-brown; undertail dark olive-brown; underwing dark olive-brown, slightly paler on coverts and paler across bases of remiges; iris dark brown to blackish-brown; bill pale steel blue or pale blue-grey; legs steely blue-grey to very pale blue, soles yellow. Sexes alike in plumage, male larger than female. Juvenile undescribed. Race *thomasi* is like nominate, except for black (not white) forehead. VOICE. Noisy. Common vocalizations include a series of "caw" notes, either piercing and nasal or hoarse and raucous, repeated at even rate of 2–3 per second, notes either on same pitch or slightly rising and falling (alternating between slightly higher-pitched clear note and lower-pitched and more complex one); and a series of bugled notes alternating between two pitches. Performs antiphonal duets: two birds face each other, less than 1 m apart on branch, and give descending series of alternating "caw" notes at normal rate, but notes of one bird filling gaps between notes of the other.

Habitat. Lower and middle montane forest, forest edge and secondary growth; also gardens. In Schrader Mts, abundant in clumps of trees (mostly native-planted casuarinas) in grasslands and in trees bordering streams through grasslands; also in disturbed forest edge. In upper Kaironk Valley, found in timbered garden areas, bush-fallow and forest. Thought to be common in or to prefer disturbed areas, thus increasing rate of hybridization with *M. belfordi* where habitat disturbance by humans increasing. Mainly 1400–2450 m, occasionally down to 1100 m; 1280–2420 m on S slopes of Eastern Highlands; in upper Kaironk Valley recorded to c. 2280 m and occasionally to 2375 m where clearings made and forest disturbed by human activity.

Food and Feeding. Diet includes insects, nectar and fruit. Usually in middle and upper storeys, often foraging high in canopy; commonly seen in flowering or fruiting trees. Noisy and conspicuous, with rather deliberate actions. Usually seen singly, sometimes in twos (probably pairs). Mutual chases in treetops.

Breeding. Nestlings recorded early Oct, fledglings mid-Jul and early Feb, and unspecified breeding in Apr. Nest a woven open basket of fine grass and fern stems, covered externally with green moss, supported or suspended in thin fork towards end of branch 2.4–4.6 m above ground. One nest contained a single nestling. No other information.

Movements. Resident; no indication of any movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. General status unclear; said to be fairly common to common, but claimed also that "pure individuals" are uncommon to rare in most of range. Interbreeding with *M. belfordi* occurs over wide area of range; suggested that some hybridization occurs naturally in undisturbed habitats in narrow altitudinal band where the two species overlap, but that large-scale hybridization is a result of extensive habitat disturbance caused initially by indigenous agriculture and possibly other human activities in more recent times. Such habitat disturbance brings the two species into contact over broader areas and permits extensive and accelerated hybridization to take place.

Bibliography. Beehler *et al.* (1986), Coates (1990), Coates & Peckover (2001), Coles (1995), Diamond (1967, 1969, 1972a), Diamond & Terborgh (1968), Gilliard (1959), Gilliard & LeCroy (1961, 1968), Gregory (1995b), Gyldestolpe (1955a), Mayr & Gilliard (1952a, 1954), McCarthy (2006), Murray (1988b), Rand & Gilliard (1967), Sims (1956), Stattersfield *et al.* (1998), Tolhurst (1991), Wahlberg (1988), Weston (1977).

55. Huon Honeyeater

Melidectes foersteri

French: Méléphage de Foerster **German:** Foersterhonigfresser **Spanish:** Mielero de Foerster
Other common names: Huon Wattled/Foerster's Honeyeater, Huon (Wattled)/Foerster's Melidectes

Taxonomy. *Melirhophetes foersteri* Rothschild and E. J. O. Hartert, 1911, Rawlinson Mountains, Huon Peninsula, north-east New Guinea.

Study of relationships within genus needed. Forms a superspecies with *M. leucostephes*, *M. belfordi* and *M. rufocrissalis*; all four, along with *M. ochromelas* and *M. torquatus*, comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Considered a race of *M. belfordi* by some authors, but may be closer to *M. leucostephes* or *M. rufocrissalis*. Monotypic.

Distribution. Huon Peninsula (Saruwaged Mts), in NE New Guinea.

Descriptive notes. 28–32 cm. Has forehead white, rest of head and neck mostly dusky black, merging into sooty brown with heavy but diffuse whitish scaling on nape, hindneck, side of neck and lower throat (forming paler collar), with large area of pale blue bare skin around eye (broader behind eye), and fine white streaking over eye, below eye and on ear-coverts; pale pink gape wattle bordered below by narrow whitish submoustachial stripe; small orange-red to red wattle behind gape wattle on side of lower throat; upperparts sooty brown to brownish-black, conspicuous greyish-white scalloping on mantle, back and

scapulars; dark yellowish-olive edges of remiges (large panel on folded wing); broad dark yellowish-olive edges of rectrices (folded tail appears yellow-olive with dark centre); underbody dark greyish-brown to dusky grey, merging into off-white in centre of belly, and spotted or scaled off-white on breast; undertail-coverts cinnamon-brown; iris pale brown; bill pale; legs greyish. Sexes alike in plumage, male larger than female and with larger gape wattle. Juvenile undescribed. VOICE.

No detailed information. Noisy. Vocalizations said to be similar to those of *M. belfordi*.

Habitat. Upper montane and high mountain forest, to tree-line; 1600–3700 m.

Food and Feeding. Few details. Noisy and conspicuous; forages in canopy and middle levels of forest. Otherwise, habits said to be like those of *M. belfordi*.

Breeding. No information.

Movements. No information; presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Adelbert and Huon Ranges EBA. Poorly known. Considered generally common.

Bibliography. Beehler (1978a), Beehler *et al.* (1986), Coates (1990), Gilliard (1959), Hammersley & Hammersley (1983), Mayr & Gilliard (1952a), Rand & Gilliard (1967), Stattersfield *et al.* (1998).

56. Ornate Honeyeater

Melidectes torquatus

French: Méléphage maquillé **German:** Zimtbrust-Honigfresser **Spanish:** Mielero Maquillado
Other common names: Ornate/Ornamental Melidectes, Cinnamon-breasted Honeyeater/Melidectes/Wattlebird

Taxonomy. *Melidectes torquatus* P. L. Slater, 1874, Hatam, Arfak Mountains, Vogelkop Peninsula, north-west New Guinea.

Study of relationships within genus needed. Present species and *M. ochromelas*, *M. leucostephes*, *M. belfordi*, *M. rufocrissalis* and *M. foersteri* comprise a group of relatively large species that differ from others in genus in size, morphology, plumage and voice. Six subspecies recognized.

Subspecies and Distribution.

M. t. torquatus P. L. Slater, 1874 – mountains of Vogelkop, in NW New Guinea.

M. t. muchalis Mayr, 1936 – Weyland Mts and S slopes of Nassau Mts and Oranje Mts, in W & WC New Guinea.

M. t. mixtus Rand, 1941 – upper slopes of Central Ranges of C New Guinea from Oranje Mts (Balim R region) E to Victor Emanuel Mts and Telefomin area.

M. t. polyphonus Mayr, 1931 – mountains of NE inland New Guinea, including Adelbert Mts, and from Bismarck Range (upper Wahgi region) E to Herzog and Kuper Ranges.

M. t. cahni Mertens, 1923 – mountains of Huon Peninsula, in NE New Guinea.

M. t. emilii A. B. Meyer, 1886 – mountains of SE New Guinea.

Descriptive notes. 23 cm; one male 48 g and female 39–45 g (nominate), male 40–58 g and female 34–44 g (*polyphonus*), one female 41.5 g (*mixtus*). Male nominate race has head and neck largely black-brown, merging to dark brown with blackish mottling on hindneck; large patch of bright orange-yellow bare skin surrounding eye (broader and tapering to rounded point behind eye), bordered above by rufous-buff rear supercilium curving over and behind rear edge of orbital patch; large rufous-brown patch behind ear-coverts; pinkish-red to red gape wattle (sometimes bordered by some rufous-brown feathering); fine silvery

streaking on ear-coverts (visible only at close range); mantle, back and scapulars greyish-brown, broadly scaled off-white to pale grey (most sparsely in centre of mantle), merging into brown on lower back, rump and uppertail-coverts (and diffusely mottled darker on lower back); upwing dark brown, olive edges of remiges (except outer two) and faint olive edges on some greater coverts (seemingly quickly lost with wear), all except inner few primaries with light brown tips; uppertail dark brown, faint olive edges of rectrices and diffuse pale tip (lost or almost lost with wear); broad white crescentic patch across throat, bold black upper breastband bordered below by pale rufous-tinged brown lower breast and centre of upper belly, this grading to buff on centre of belly and to off-white on rest of underbody, with bold black blotches on side of breast (can appear as second partial breastband) and belly and along flanks (sometimes some scattered patches elsewhere), and diffuse blackish mottling on undertail-coverts; undertail brown; underwing very pale rufous-brown with brownish-grey trailing edge and tip; iris blackish-brown; bill light blue-grey, becoming pale green-blue near base; legs blue-grey. Female is similar in plumage to male but much smaller, and bare parts somewhat duller, iris dark brown, bill steel-grey to pale blue, legs steel-grey, bare facial skin bright yellow (less orange), gape wattle slightly paler. Juvenile is like adult but duller, with less prominent pale scaling above, buff (not rufous-brown) breast, dusky dark blotches on underbody, bill pinkish-grey with orange-yellow cutting edges and gape, legs greyish-pink, gape wattle apparently as adult. Races differ mainly in presence or absence of throat wattle, in darkness of plumage, particularly rufous-brown of breast, and in size of white throat patch: *polyphonus* is larger than nominate, slightly darker above, with rufous-brown supercilium, rufous-brown hindneck and black-brown mantle to back (birds in Adelbert Mts larger and slightly paler above), noticeably darker and more rufous below, has pinkish wattle along side of throat; *mixtus* is large, with mixture of racial characters (but not intermediate), differs from previous in having rudimentary or no throat wattle, slightly darker upperparts lacking rufous tinge on nape, more blackish rump, and much paler rufous-brown to rufous-buff breast; *nuchalis* is smaller than preceding two races, similar to nominate (and lacks throat wattle), from which differs in stronger rufous supercilium, darker upperparts, with sooty-brown nape and blacker (less greyish) mantle, back and scapulars with narrower and less conspicuous white scaling, slightly smaller white crescent on throat, paler rufous-brown breast, bolder blackish markings on side of belly and flanks; *emilii* differs from others in reduced white throat patch (confined to centre of throat), and long, broad orange-yellow throat wattle adjoining gape wattle, otherwise similar to nominate but with stronger rufous-brown below (juvenile lacks throat wattle, and birds in otherwise adult plumage with no throat wattle likely to be immatures; not known when adult wattle attained); *cahni* is fairly small and comparatively dark above, particularly on head and hindneck, but paler rufous below, has obvious throat wattle smaller than that of last race. VOICE. Noisy at times, with loud raucous vocalizations. Song of repeated loud, rollicking but varied phrases, e.g. in Wahgi Valley c. 8 throaty, hollow, staccato notes with rises and falls in pitch, lasting c. 2 seconds, "tok-tar-chii-cher-chu-chii-cher-chu", or a variant shortened to 5 notes, "chii-cher-chu-chii-cher"; described also as complex disyllabic gurgles, the first higher-pitched. Also brief, mellow, whistled "top", "tip" or "tup" repeated several times at intervals of 3–5 seconds, wheezy whistled note, short rasping "whogh", and repeated "too-ouu".

Habitat. Lower and middle montane forests, forest edge, open secondary growth, scrub, agri-gardens and cultivation, and trees in gardens of towns and villages, especially of inland montane valleys; typically prefers semi-open habitats or secondary growth and other disturbed habitat. From c. 950 m (occasionally 750 m, e.g. in Tabubil region) to 1900 m in E New Guinea, to 2200 m in Snow Mts; mainly 1200–1700 m in Central Ranges (to 1800 m at Simbai); c. 900–1700 m in Huon Peninsula and c. 1300–1600 m (summits) in Adelbert Mts; to c. 1600 m in Vogelkop. Co-exists with *M. belfordi* at 1800 m on Mt Kaindi.

Food and Feeding. Diet invertebrates, mainly insects and their larvae, including Lepidoptera, bugs (Hemiptera) and beetles (Coleoptera); also nectar and small fruits, and also takes pulp from larger and hard-shelled fruits opened by Rainbow Lorikeets (*Trichoglossus haematomodus*). Needles from an introduced pine (*Pinus*) recorded in stomach contents. Forages from canopy to lower middle stages of forest and in flowering or fruiting trees, searching among foliage, at flowers (of trees, epiphytes, bananas) and at fruits; occasionally at ground level, and seen to forage at cluster (4-m diameter) of flowering *Mitrastemma yamamotoi* (a terrestrial root parasite), which birds visited persistently in mornings but more frequently in afternoon, usually descending cautiously and probing flowers while gripping vertical stem. Active, and conspicuous in gardens of villages and towns, also commonly in forest interior. Forages at a site for short time before flying to new site 30 m or more distant. Usually singly, in twos (probably pairs) or in small groups of 3–6 or more individuals, and sometimes congregates in flowering or fruiting trees; sometimes feeds with other species, including small parrots (Psittacidae) and Sclater’s Whistler (*Pachycephala soror*). Will defend food trees, or parts of them, attacking and driving off conspecifics and other species, e.g. in fig tree (*Ficus*), rapid aggressive responses towards *Melilestes megarhynchus*, *Pycnopygius cinereus* and Fan-tailed Berrypecker (*Melanocharis versteri*) prevented these species from using the tree for more than a few moments at a time. When foraging on *Mitrastemma yamamotoi* on ground was often attacked by *M. belfordi*, which appeared to control foraging at the patch in mornings.

Breeding. Few reliable data. Appears to breed in most months from late wet season through to late dry season: nestlings late Mar to early May, and fledglings late Mar to Apr, Jun, Aug–Sept and early Nov. Nest a neat cup (external diameter of one was 12 cm), placed moderately high up in horizontal fork, one c. 20 m above ground near top of tree. No other information.

Movements. No indication of any movements; probably sedentary.

Status and Conservation. Not globally threatened. Generally fairly common to common in some regions, and scarce to rare elsewhere. Suggested that, in view of preference for forest edge, open second growth and trees in gardens, this species is, along with Brown-breasted Gerygone (*Gerygone ruficollis*), probably one of the mid-montane bird species that have profited most from human activities.

Genus *MELIARCHUS* Salvadori, 1880

57. San Cristobal Honeyeater

Meliarchus sclateri

French: M  liphage de San Cristobal **Spanish:** Mielero de San Crist  bal
German: Rostschwanz-Honigfresser

Other common names: San Cristobal/Makira Melidectes, Graceless Honeyeater

Taxonomy. *Philemon Sclateri* G. R. Gray, 1870, San Cristobal, Solomon Islands. Relationships uncertain; has sometimes been placed in genus *Melidectes*, and has also been placed close to monotypic *Acanthagenys*. Monotypic.

Distribution. San Cristobal, in E Solomon Is.

down side of neck olive-brown, heavily streaked or mottled off-white to creamy buff on malar area (malar area sometimes appears wholly off-white to creamy buff at base of bill), more finely and sparsely streaked off-white on ear-coverts; mantle to rump dark olive-brown with varying olive-green wash, blackish scaling on middle back; uppertail-coverts and uppertail rufous-brown (rufous-brown shafts of rectrices), fine and faint olive edges of rectrices (seemingly readily lost with wear); upperside dark olive-brown to blackish-brown, with diffuse olive tips on marginal and median coverts, and fine olive-green outer edges of greater coverts and remiges (strong olive-green wash on folded wing); chin and throat off-white to very pale grey-brown, finely and sparsely streaked olive-brown, and merging into slightly darker grey-brown breast, belly, vent and flanks, boldly streaked olive-brown across breast and merging to more diffuse and fainter brownish streaking or mottling on rest of underparts; undertail-coverts and thighs light rufous-brown; undertail light grey-brown; iris off-white to pale greenish-grey or pale greenish-brown, eyelid pale blue or whitish with yellow, green or brownish tinge; bill cream to pale creamy yellow, base of upper mandible pale greenish, gape whitish; legs pale grey to blue-grey, sometimes with yellow wash. Sexes alike in plumage, male larger than female. Juvenile is like adult, but ground colour of head, neck and side of throat paler and less strongly olive, dark olive-grey, with yellowish tinge on side of head and underbody, streaking below more diffuse, and rump and uppertail-coverts more strongly rufous. **VOICE.** Noisy, with large variety of mostly harsh and loud, twangy whistles, honks and croaks. Calls include loud, sonorous and twangy “che  k che  k che  k”, “chichichichi”; clear, melancholy disyllabic whistles, “tee woo”, “cheowi” or “oo-ow ooup”, sometimes preceded by rapid squeaky “whichichi”; high-pitched, shrill mewing “chew  k” or “duit, duit, duitw  it”; loud “wit...wit...wit...” from exposed perch during rain while calling or counter-calling with other birds; in alarm, undulating “chrr-  r-  r-  r” ending in squawk. One call described as a repeated series of loud, raucous and nasal slurs possibly refers to one of aforementioned calls.

Habitat. Primary forest, less often tall secondary forest and forest edge, occasionally foraging out into coconut plantations. In primary forest, most abundant in hill forest, with lower densities in

montane and lowland forests. Sea-level to at least 900 m, mainly above 450 m; uncommon in coastal lowlands except near rivers.

Food and Feeding. Diet includes insects and probably nectar. Forages within dense forest canopy, less often in substages; also in isolated trees and coconut plantations. Searches at inflorescences and clumps of flowers; often appears to be seeking insects, but seen to probe flowers. Movements ungainly. Seen singly, in twos and in small parties of up to five individuals; occasionally in mixed-species flocks. Pugnacious, often chasing one another; seen also to displace other species, including Chestnut-bellied Monarch (*Monarcha castaneiventris*), Golden Whistler (*Pachycephala pectoralis*) and *Myzomela tristrami*.

Breeding. No information.

Movements. Resident; occasional local movement between foraging habitats.

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA. Confined to a single island, where common to abundant. Maximum daily counts of 37 individuals between 450 m and 900 m. Abundant in hill forest, where 220 encounters/km  ; 110 encounters/km   in montane forest and 24/km   in lowland forest; in secondary forest and coconut plantations combined, 5 contacts/km  .

Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Doughty *et al.* (1999), Finch (1985), Galbraith & Galbraith (1962), Gray (1870), Hartert (1929), Mayr (1932, 1945b), Mayr & Diamond (2001), Parkes (1980), Rothschild & Hartert (1908), Stattersfield *et al.* (1998).

Genus *MANORINA* Vieillot, 1818

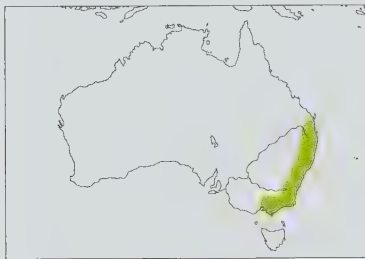

58. Bell Miner

Manorina melanophrys

French: M  liphage    sourcils noirs **German:** Glockenhonigfresser **Spanish:** Mielero Cejinegro
Other common names: Bellbird, Bell Minah/Mynah

Taxonomy. *Turdus melanophrys* Latham, 1801, Nova Hollandia = region of Port Jackson, New South Wales, Australia. Monotypic.

Distribution. E & SE Australia on and E of Great Divide, from SE Queensland (S from Gympie) S to E Victoria (W as far as E Melbourne, and with isolated colony just NW of Melbourne).

Descriptive notes. c. 18.5 cm; male 24.2–45 g, female 25–33 g. Robust honeyeater (but smallest of genus). Plumage is mostly olive-green above and slightly paler yellowish-green below, with grey suffusion on crown and ear-coverts, blackish forehead and malar stripe, yellow loreal patch, and triangular patch of bare red-orange skin behind eye; upperside-coverts and primaries grey-brown, with fine grey outer edges and tips on all except outermost primaries, greyish-olive tertials and secondaries with fine yellowish-olive outer edges and tips, tertials also with dark grey-brown fringe on inner web; undertail greyish olive-green, underwing brownish-grey;

iris dark brown; bill and legs yellow to orange-yellow. Sexes alike in plumage, male slightly larger than female. Juvenile is duller and browner than adult, and without bright bare facial skin behind eye, largely olive-brown above, forehead and malar stripe contrasting little with crown, loreal patch dull yellow, gape puffy and yellow, upperside-coverts brown with yellowish-brown fringes, yellow-olive underbody heavily mottled with light grey-brown on breast and lightly mottled elsewhere; immature as adult, but bare skin behind eye initially yellow to pale orange, gradually becoming rich orange to red-orange by c. 9 months. **VOICE.** Repertoire complex; 18 adult calls described (six given only by female, one only by male), many with variants. Most conspicuous call a loud, musical and pure bell-like “tink”, “ting” or “ping”, loud and pure, carries well and can be difficult to locate, given incessantly through day (although colonies may be quiet for periods) and a characteristic sound of Australian bush; appears to be a general interspecific territorial call, as well as an intraspecific contact call. Other calls predominate during dawn and dusk choruses. Those given by both sexes are “Mew call”, in variety of circumstances when near nest or young; highly varying “Chip call” when alarmed or mobbing, but also as morning call (c. 35 minutes before dawn), during intraspecific chases, and during displacements; loud “weeek” often given after an alarm and may attract birds to mobbing, also commonly at dawn and dusk (may help to co-ordinate roosting), often given antiphonally; “cek” in response to aerial predator, when suddenly startled or during intraspecific chases; “mmm” in response to ground predators, including humans near nest or young, or when startled; “brurr” when physically contacting another bird (of same or another species); “waw”, usually given with wings held raised during mobbing, sometimes when displacing another or during intraspecific chases; “screeet” occasionally given when handled; shrieking “scree” when nest or young approached by human; and “In call” (possibly only by male). Female calls (“Chuk-a-choo”, “Wheel”, “Whistle”, “Wee”, “Ip” and “Whit”) given during courtship (and not when attending nestlings or in non-breeding periods), thought to function in courtship of males, in synchronizing reproduction between mates, in reinforcing pair-bond, in mate-guarding and in maintaining contact. Adult male has one sex-specific call (“Oar call”), thought to function in establishing and reinforcing pair-bond; varies individually, given mainly during courtship, sometimes during incubation; usually preceded by In call, and may be given immediately after Chuk-a-choo of female. Gradations between different calls appear to exist. For most calls, individual differences in some characteristics (strong evidence of individuality in Chuk-a-choo of female, Oar of male, and Mew calls).

Habitat. Mainly open sclerophyll forests and woodlands, and adjacent vegetation with dense shrubby understorey, in broad gulleys in foothills or coastal plains; usually concentrated in patches of forest where eucalypts infested with psyllids and, sometimes, showing signs of dieback. Prefers dry open eucalypt forest and woodlands, usually with sparse shrub layer, sometimes with secondary layer of trees; wet sclerophyll forest supporting lower layers of trees and shrubs, and including stands regenerating from logging (but not wet montane forests); and riparian eucalypt forests and woodlands, especially open woodlands with dense shrub layer, also other open eucalypt woodlands bordering creeks and rivers and with dense understorey of native shrubs (e.g. *Leptospermum* and *Acacia*) or exotic shrubs such as blackberry (*Rubus*) or sapling eucalypts. Often at ecotones with preferred habitats and rainforest, but rarely in rainforest proper. Commonly in remnant bushland, or in parks and gardens with retained eucalypts, dense understorey vegetation (native and exotic),

and natural watercourses in city suburbs. Occasionally in coastal scrub, or scrubby gulleys with *Lantana camara* thickets.

Food and Feeding. Diet primarily invertebrates; also nectar (usually when abundant), manna and honeydew, occasionally fruit. Invertebrates mainly insects, including larvae and insect products, particularly psyllids and their lerp; also some spiders (Araneae) and pseudoscorpions (Pseudoscorpiones). Forages mainly in canopy, typically above 8 m (and to 15 m or more); often descends to middle storeys and undergrowth in low trees and saplings; occasionally on ground. In Victoria, used height stages more evenly where dense shrub layer and lower layer of trees present than in vegetation with little understorey. Forages mainly among foliage, less often on bark, on twigs or at flowers. Main methods gleaning and probing (mainly into crevices of bark), less often sallying, including sally-strikes at prey in air and sally-hovering to take items from flowers and foliage, and occasionally by flush-pursuit; often hangs upside-down to reach prey. When feeding on lerp, does not always take the psyllid larvae (but many are detached along with lerp and are ingested); removes lerp with bill and draws it into mouth with tongue; also licks leaf surface around lerp, where honeydew accumulates. At Yellingbo (Victoria), spent 10–26% of daytime in foraging, and 60–97% of that time in feeding on lerp; at Olinda (Victoria), spent 36% of daylight hours in eating lerp. Within colonies, individuals reduce predation rates on psyllids by aggressively excluding other birds and by defending colony territories of sufficient size so as not to consume entire psyllid populations themselves, and removal experiments have shown that large psyllid populations are rapidly consumed by other species when present species absent; was therefore suggested that this miner farms psyllids, but others interpret the behaviour as little different from defence of any renewable resource; relationship between this species and psyllids perhaps more subtle than this, especially if the birds are intentionally taking lerp and protecting the psyllid. Non-breeding members of colony occupy foraging ranges that overlap with those of one or more breeding pairs. Mean individual ranges 0.22–0.25 ha, and size appears not to vary greatly with age, sex or breeding status.

Breeding. Breeds throughout year, with peaks in Aug and Jan–Apr and little breeding May–Jul; at two sites in Victoria recorded in all months, mostly Aug–Jan at Bundoora (where positively correlated with rainfall) but most breeding activity Aug–Apr at Healesville (wetter than Bundoora, peak coincided with period of lowest rainfall and highest temperatures, in Jan–Feb); usually multi-brooded, breeding females at one site in Victoria made 0.65 nesting attempts per month. Obligate co-operative breeder, living all year in permanent colonies of 8–200 or more individuals, complex social organization consisting of a number of monogamous breeding pairs, each occupying discrete core area, and non-breeding members; colony defended by all members; nesting within colony may not be strongly synchronized, but seems fairly synchronous among females within a coterie (discrete aggregation of individuals within colony). Female appears to select nest-site and she alone builds nest, a thin and often transparent cup of dry grass culms, spider web, fine twigs and rootlets, sometimes lined with pieces of fresh leaves (other materials used in construction include fine shreds of bark, cocoons, broad soft leaves, flowers, seed pods, casuarina needles, lichen, moss, feathers, hair, plastic, plant down), external diameter 7.6–10.2 cm, depth 5.1 cm, internal diameter 6.4–7 cm, depth 3.8–4.4 cm; suspended by rim 0.3–2.5 m (mean in various studies 2.07–2.8 m) above ground, usually in horizontal (less often upright) fork in dense undergrowth, usually not at edge of nest plant. Clutch 1–3 eggs, usually 2 (mean in various studies 1.8–2.01), 4 eggs in one nest almost certainly the product of two females; incubation by female, usually beginning when clutch complete, incubation period at Healesville 12–18 days, mean at Bundoora (from laying to hatching of last egg) 14.4 days; chicks fed by both breeding adults and by auxiliaries (up to 20 attend nest), nestling period at Healesville 10–15 days, mean at Bundoora (between hatching of last egg and fledging of last nestling) 11.7 days; fledglings fed by parents and auxiliaries. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*) and possibly by Fan-tailed Cuckoo (*Cacomantis flabelliformis*). From several studies, success (young fledged per egg laid) 41–57%; of 153 nests at Bundoora, 58 (37.9%) fledged at least one young, mean 0.62 fledglings per attempt; of 243 nests at Healesville, 84 (34.6%) fledged at least one young; at Bundoora, mean of 3.83 fledglings per female lifetime. During six-year study in Victoria, more than 70% of young disappeared before mean age of dispersal (8 months after fledging), and probability of nestling surviving to mean age of first breeding (15.4 months) 0.07, but a bird that survived to age of first breeding would live an average 1.7 more years; mean annual survivorship of breeding males 67.5% and of breeding females 59.4%.

Movements. Sedentary. Colonies usually permanent, occupying sites for many years, members rarely moving beyond colony boundary. Distribution of colonies can vary over time, and all or part of colony may move to new site, e.g. part of colony at Bundoora moved between Nov and Mar to new site 400 m away, and another colony shifted 110 m over two years. Small movements in territorial boundary of colony thought to result from changes in quality of vegetation or interactions with other species, such as *M. melanocephala*. New colonies sometimes established near or distant from existing ones (e.g. up to 10 km from nearest colony). Vagrants occur up to c. 320 km from nearest known colonies.

Status and Conservation. Not globally threatened. Locally common. At Yellingbo (Victoria), recorded density of 6.4 birds/ha; at Bundoora colony, densities of 7.9–17.9 birds/ha (1994) and 12.5 birds/ha (1984). Historical records from W of Great Divide in New South Wales, and historical reports of “bellbirds” on Murray R were possibly of this species. Individuals imported into New Zealand in 1874, but not known if any were released into the wild; if they were, they did not become established. Can be adversely affected by natural processes and human activities, including fire (both wildfire and controlled or intentional burning), clearing, and stream modification, resulting in loss of understorey in preferred habitats; colonies have been lost and created at sites throughout range. This species has become closely linked to large-scale eucalypt dieback in forests of E Australia (“Bell Miner-Associated Dieback”) which has resulted in loss of tens of thousands of hectares of forest and is of special concern to commercial forestry interests. Psyllids thrive in colonies of this meliphagid, often to detriment of trees; when miners are removed, colony site is invaded by many other insectivores, which within a few months greatly reduce abundance of lerp-producing psyllids. Mechanisms of this dieback, however, not fully understood, and habitat disturbances, such as hydrological stress, soil pathogens and changed fire regimes, are implicated in creating conditions suitable for psyllid infestations and subsequent colonization by this miner, leading to dieback; certainly, removal of the miners does not always result in forest recovery. Overall, Bell Miner-Associated Dieback thought to be a significant threat to sustainability of moist eucalypt forests of NE New South Wales and SE Queensland, and thus to biodiversity conservation on a national scale.

Bibliography. Anon. 59. Noisy Miner

Manorina melanocephala

French: Méléphage bruyant **German:** Weißstirn-Schwatzvogel **Spanish:** Mielero Chillón
Other common names: Southern Black-backed Minah/Mynah

Taxonomy. *Gracula melanocephala* Latham, 1801, Nova Hollandia = region of Port Jackson, New South Wales, Australia.

Forms a superspecies with *M. melanotis* and *M. flavigula*. Rarely, hybridizes with latter. Geographical variation on mainland apparently clinal, N populations tending slightly paler above (with little or no yellow-olive wash, more contrasting blackish and white tones) than S ones (more pronounced yellow-olive wash); also, wing becomes progressively longer from N to S (though one study found no significant regional differences in lengths of wing, tail and culmen). Two additional races recently proposed are *titaniota* (described from 47 km W of Fairview Station, in Cape York Peninsula) and *lepidota* (from 17 km W of Nyngan, in New South Wales), but much further study required in order to determine validity of these. Two subspecies recognized.

Subspecies and Distribution.

M. m. melanocephala (Latham, 1801) – E & SE Australia from NE Queensland (E base of Cape York Peninsula) S, extending W to inland slopes and plains of Great Divide, to SE South Australia (E from Mt Lofty Ranges) and Victoria.

M. m. leachi (Mathews, 1912) – N & E Tasmania.

Descriptive notes. 24–28 cm; male 40–91 g, female 46–74 g and unsexed 54–90 g (nominate), male 70–87 g, one female 72 g and unsexed 64–1–94.2 g (*leachi*). Nominative race has head, neck, upperbody and breast largely grey, with off-white forehead, lores, chin and throat; broad black band extending over crown, through eye and in crescent around rear ear-coverts, joining black malar stripe from base of bill; bold patch of bare yellow skin behind eye; grey-black line down centre of throat; fine white scaling on nape and hindneck grading to slightly broader dusky-and-white scalloping on throat and upper breast, and to fine dusky mottling and

narrow white scaling on mantle, back and scapulars (saddle also faintly tinged olive-yellow); uppertail grey, feathers with narrow olive-yellow edges and bold white tip; tertials and most of upperswing-coverts grey, contrasting with dull blackish-brown lower edge of inner wing (outer coverts) and rest of remiges, olive-yellow edges of outermost tertial, secondaries and inner primaries (narrow panel on folded wing), outer primaries narrowly tipped white; underbody below breast white, pale grey wash on flanks and thighs; undertail dark grey with broad white tip; underwing dark grey, slightly darker wingtip and diffuse off-white patch on bases of primaries; in worn plumage, mantle, back and scapulars become darker and lose white scaling, upperswing more uniformly dark; bill darker and contrasts with paler rump and uppertail-coverts; iris red-brown to dark brown; bill orange-yellow to yellow; legs orange to brownish-orange. Sexes alike in plumage, male larger than female. Juvenile is very similar to adult, but band over crown duller and finely scaled paler, merging into black-brown on nape and hindneck, with upperbody suffused brown, only obscure white scaling on hindneck, side of neck and breast, median and greater upperswing-coverts finely tipped brownish (diffuse narrow wingbars), white primary tips broader, bill tipped dusky, gape initially puffy orange-yellow, and bare skin behind eye duller, yellowish-grey. Race *leachi* is larger than nominate, plumage very similar but off-white scalloping on hindneck finer, yellow-olive wash on scapulars and back stronger, off-white fringes at tips of scapulars and feathers of mantle and back indistinct, and white tips on outer 3–4 rectrices broader. **VOICE.** Noisy, with complex repertoire. Detailed study described twelve adult vocalizations, and dawn song, which comprises combinations of various other vocalizations. Main adult calls are: “Tiu call”, consisting of repeated rhythmic phrases of 2–5 “tiu” notes, with many variants, e.g. low whistled “teu-teu...teu-teu”, difficult to locate; “Woo”, of repeated whistled “woo” notes, also with many variants, e.g. up to 12 notes, or repeated phrases of 2–6 “woo” notes; “Aerial predator alarm call”, a series of high-pitched upslurred whistled “woo” notes; “Wee call”, a series of “wee” notes; “Chur”, a series of “chur” notes, like previous but lower-pitched and harsher, at high intensity sounding like nasal miaowing, as alarm in response to ground predator and non-predatory bird and during mobbing; “Yammer”, a rapid rhythmic series described as a soft staccato plaintive yammering; “Long flight call”, a series of 4 ascending notes, or constant low chatter; “Harsh wee call” of 5–7 notes, like those of long flight call but harsher; “Cue”, a series given by bird when chased; “Q4 call”, a rhythmic throaty chuckling of usually 4 (sometimes 5) notes, difficult to locate; a varying “Chip call”; and “Distress call” when bird held in the hand. Dawn song a chorus (from colony) of clear whistled notes, including antiphonal singing and with Tiu, Woo and Wee calls and others, lasts for up to 20 minutes and audible over long distance; mainly before sunrise but also at dusk, and sometimes by single individuals. Other calls include rapid twittering “tse-tse-tse...” during copulation, and soft chuckling. Much individual variation. Some calls differ little in structure within colonies, but markedly between colonies. During breeding the Tiu calls of male are often answered, usually within 4 seconds, by a Q4 call from a female.

Habitat. Mainly dry open sclerophyll forests and woodlands, especially grassy associations with few or no shrubs in understorey, including savanna woodlands, and typically dominated by *Eucalyptus*, or mixed associations dominated by *Eucalyptus* with cypress-pine (*Callitris*), or *Acacia* or casuarina or, less commonly, *Melaleuca* and *Erythrophloeum*, or *Banksia*. Sometimes in open riparian or floodplain-woodlands with understorey of chenopods (*Atriplex*), *Acacia* or lignum (*Muehlenbeckia*). Not commonly in mallee eucalypt woodlands or shrublands. Often at edges of wooded habitats, or in open areas within or bordering forests and woodlands, such as roadsides; also in remnant forests and woodlands surrounded by cleared land, and often more abundant in such habitats than within large undisturbed patches. Commonly in modified habitats, particularly lightly wooded agricultural land, and common in cities and towns. Sometimes in other habitats, including wet sclerophyll forest, *Acacia* shrubland or woodland, e.g. remnant brigalow (*Acacia harpophylla*) scrub, or coastal heathland or scrub. Plains to c. 1200 m, and commonly along watercourses on inland slopes and plains.

Food and Feeding. Primarily invertebrates and nectar; also fruit, seeds, occasionally small vertebrates (frogs, reptiles). Invertebrates mainly insects, but also spiders (Araneae), annelids, centipedes (Chilopodidae) and pseudoscorpions (Pseudoscorpiones). Forages at all levels, from canopy to low shrub layer, searching among foliage, at flowers, on large and small branches, twigs and trunks, and often on ground. In study in SE Queensland, foraging behaviour and use of substrates found to differ with density of colony, presence of other species and complexity of habitat. Invertebrates taken by gleaning or by sallying, including sally-hovering, from plant substrates or ground; nectar taken by probing flowers. On ground, walks or hops, searching in soil or litter, even turning litter or animal droppings. Occasionally hangs upside-down to reach food items. Conspicuous,

confiding. Highly social: colonial and usually gregarious in all activities; forages almost solely within colony boundaries throughout year. Usually seen in small groups of 5–25 individuals, occasionally alone or in twos; sometimes in larger numbers at sources of abundant nectar. Once seen to forage with *M. flavigula*. One of the most aggressive honeyeaters, nearly always attacks and sometimes kills other avian species (including non-predatory birds) crossing colony boundaries, resulting in almost exclusive use of area and its resources by colony; a few, often larger, species, such as Grey Butcherbird (*Cracticus torquatus*) and Laughing Kookaburra (*Dacelo novaeguineae*), reside in low numbers in colonies, usually close to edges.

Breeding. Recorded in all months, with peak apparently in winter–spring; in SE Queensland mostly Jul–Nov, possibly slightly later farther S; multi-brooded, laying up to six clutches per year. Obligate colonial and co-operative breeder, colonies ranging in size from a few individuals to several hundred (c. 400 birds in one colony), and up to 22 males and one female attending a single nest; both males and females promiscuous; laying not highly synchronized in colony. Nest built by female alone, a deep but frail cup (sometimes sturdier) of twigs or grasses or both, occasionally incorporating rootlets, bark, leaves, vine tendrils, hair, wool or fur, spider web, feathers and insect egg cases, lined with wool, hair, fur, fine rootlets and bark, and occasionally feathers, flowers, plant down or fine grasses, sometimes includes artificial materials; in SE Queensland, outside of cup usually of small twigs and interior of grasses, bound with spider web, and lining usually a rounded pad of fibres from cocoons of processional caterpillar (Lasiocampidae); external diameter 15–17.8 cm, depth 9–11.4 cm, internal diameter 8–8.9 cm, depth 5.5–6.4 cm; usually supported in fork or on twigs or branchlets, often near end of low branch, 0.2–30 m (mean 6.3 m) above ground. Clutch 2–4 eggs (larger clutches almost certainly the product of two females), mean throughout range 2.9; incubation by female alone, period 15–18 days; chicks brooded by female, fed by both parents and by auxiliaries, nestling period c. 13–16 days (usually 16 days); fledglings fed by breeding male (rarely by breeding female) and by auxiliaries, in SE Queensland began to obtain own food 26–30 days after fledging but still fed by others in group until 35 days (occasionally longer); young often return to nest for several days. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*). For 270 eggs in 105 nests where outcome known, 0.89 fledged young per nest; of 378 nests, 284 (75%) produced at least one fledged young; of 41 nests at one site in SE Queensland, 24 (59%) produced at least one fledged young, and mean number of fledglings/nest significantly lower in harsh season (1.11) than in good season (2.44).

Movements. Sedentary. Some limited dispersal to and from colonies.

Status and Conservation. Not globally threatened. Common; one of the commonest native birds in cities and towns. Recorded densities of 7.8–10.4 birds/ha in SE Queensland; at several mainland sites 0.02–4.9 birds/ha, and at one site in SE Tasmania 0.01–0.05 birds/ha. Has largely benefited from clearing and fragmentation of native vegetation, preferentially occupying small remnants (size less than 20 ha) of forest and woodland and edges of larger blocks; has increased in such habitats, and appears to have spread to new sites within its overall distribution (which appears not to have changed markedly). Dominates many urban and rural habitats, and has adverse effect on avian diversity and abundance by aggressive exclusion of other birds from colony area; experimental removal of this miner is followed by influxes of other meliphagids and other insectivorous birds. Further, present species may contribute to decline of rural trees and spread of eucalypt dieback through its maintenance (by excluding of other insectivorous birds) of high levels of herbivorous insects in such landscapes. Dominates edge habitats, too, effects penetrating as far as 150–300 m from edges, which has major effect on width of corridors or expanse of remnants needed to ensure areas free of this species; can devalue conservation effort if corridors and remnants of insufficient width to provide suitable habitat for other species. Studies have shown that eucalypt plantings can be made less susceptible to dominance by this miner by the addition of a shrubby understorey combined with *Acacia* species; similarly, in revegetating slow-growing buloke (*Allocasuarina luehmannii*) woodland, fast-growing eucalypts are often included, resulting in domination of replantings where eucalypt density 5/ha or greater. Has been suggested that dominance of remnant woodland and forest by present species is now the most important threat to certain bird communities in E & SE Australia. The only meliphagid known to have been introduced outside its country of origin: released in Three Sisters Is (off San Cristobal), in SE Solomons, in 1950s, but doubtfully extant (not recorded during surveys in 1990, and no evidence of continued presence); possible unsuccessful attempted introduction in New Zealand in 19th century, but reports may have confused this species with Common Myna (*Acridotheres tristis*).

60. Black-eared Miner

Manorina melanotis

French: Méléphage à oreillons noirs **German:** Malleeschwartzvogel **Spanish:** Mielero Orejinegro
Other common names: Dusky Miner/Minor

Taxonomy. *Myzantha melanotis* F. E. Wilson, 1911, Mallee, Victoria = c. 30 km north of Cowangie (Kow Plains), north-west Victoria, Australia.

Forms a superspecies with *M. melanocephala* and *M. flavigula*. Often treated as conspecific with latter, and hybridizes extensively with it (to extent that genetic introgression threatens survival of present species); analyses of mitochondrial DNA, however, suggest that the two should be treated as separate species. Monotypic.

Distribution. Semi-arid mallee in lower Murray–Darling Basin of NW Victoria and CE South Australia.

Descriptive notes. 23–26 cm; 43.5–60 g. Plumage is largely grey above, with dull olive forehead merging into grey of crown, black facial mask (from bill narrowly over and below eye to ear-coverts) bordered below by indistinct yellow moustachial stripe, grey submoustachial stripe and thin blackish

malar stripe, and small patch of bare yellow skin at rear of eye (extending narrowly above and below rear half of eye); in fresh plumage, fine greyish scaling on side of neck and mantle, back and scapulars; uppertail mostly grey-black, broad paler grey tip and narrow olive-yellow edges at bases of rectrices; upperwing black-brown, secondary coverts and tertials contrastingly dark grey, fine paler grey tips on median and greater coverts, greater also with narrow olive-yellow edges, olive-yellow outer edges of remiges (prominent diffuse yellowish panel on folded wing), outer primaries also have thin white tips when fresh; chin to breast with black-

ish-and-white scalloping merging into white below, grey wash on flanks and thighs; sometimes yellowish tinge on chin; undertail dark grey with slightly paler grey tip; underwing dark grey, diffuse whitish patch across bases of primaries; iris dark brown; bill and gape yellow to orange-yellow; legs orange to brownish-orange. Sexes alike in plumage, male larger than female. Juvenile is very like adult, differing in pale brown suffusion on upperbody, no white scaling on side of neck, brownish suffusion on tail tip, more uniformly grey breast with less obvious scalloping and varying brown wash, narrow pale brown tips on median and greater upperwing-coverts (narrow wingbars), clearer whitish fringes at tips of primaries, and bill and eye patch slightly duller yellow. Voice. Poorly described. Most calling in early morning and during breeding. Calls harsh and grating, include a series of quiet single notes given at intervals of 1–2 seconds; alarm calls not unlike those of *M. flavigula* when flushed; one bird approaching nest to incubate uttered low warble.

Habitat. Mature intact tracts of semi-arid mallee eucalypt woodland, unburnt for at least 45 years, on a range of soil types including deeper sandy dune and sandy swale areas with good cover of spinifex (*Triodia*), and in swales on heavier soils with little spinifex. Suitable habitat includes both mallee–*Triodia* associations and mallee with open shrubby understorey (e.g. of *Acacia*, *Beyeria*, *Westringia*, *Olearia* or chenopods such as *Atriplex*) in continuous tracts at least 2 km from natural or artificial clearings, and aforementioned vegetation with total continuous area of at least 13,000 ha (regardless of age since fire); absence of grazing also important.

Food and Feeding. Diet primarily invertebrates (mainly insects, also spiders), occasionally nectar. Forages at all levels, from canopy to ground. Searches among foliage of trees and shrubs, at flowers (e.g. of *Melaleuca*, *Eucalyptus*, *Eremophila*), on and under bark of branches and trunks of mallee trees (usually eucalypts), and often on ground among leaf litter. Forages mainly by probing and gleaning, less often by sallying; on ground, appears not to turn leaf litter but to search among it. “Pure” individuals tended to forage in one place for 10–90 seconds and then fly off, whereas hybrids foraged at sites for longer periods (up to 4 minutes). Colonial, and normally in small groups.

Breeding. Not well known. Recorded in Sept–Dec, probably extending into autumn. In loose colonies, nests sometimes as little as 25 m apart; usually (possibly always) breeds co-operatively. Nest made of twigs, pieces of dodder (*Cassytha*), grasses and spider web, lined with grasses, including spinifex, 1.5–4.5 m above ground in vertical fork of larger branch or in dense epicormic growth, usually in denser foliage in tall mallee but sometimes among small twigs or in dodder (usually growing on eucalypt), mainly in mallee eucalypt but also in *Myoporum*, *Santalum*, *Melaleuca*, *Acacia* or *Callitris*. Clutch 2–3 eggs; incubation by at least three individuals at one nest; no information on duration of incubation and nestling periods. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*).

Movements. Colonies sedentary, apparently within fairly large ranges, but few hard data. Tends to stay within area of c. 10 ha when breeding, but appears to range more widely outside breeding season. In Victoria, one colony of two “pure” individuals and nine hybrids ranged over area of at least 60 ha. In the past transitory individuals were reported, possibly indicating wider dispersal or movement at times. Seen to move through *Allocasuarina* woodland and across clearings, indicating that small areas of non-mallee habitat are not a barrier to dispersal.

Status and Conservation. **ENDANGERED.** Restricted-range species: present in South-east Australia EBA. Rare and local; one of Australia’s rarest bird species. Most of remaining colonies confined to mallee NW of Renmark, in E South Australia. Discovery of significant numbers N of Murray R in E South Australia has greatly enhanced this species’ prospects of survival. Bookmark Biosphere Reserve, which holds most of known populations, is estimated to support 501 colonies containing c. 3758 phenotypically pure individuals, c. 2255 hybrids, and small numbers of *M. flavigula*; smaller population in Murray-Sunset National Park, in NW Victoria, consisting of 53 pure or hybrid colonies. Estimated effective population, however, is an order of magnitude smaller owing to male-biased sex ratio and the species’ complex colonial and co-operative social organization: in Bookmark estimated to consist of 390 pure individuals and 234 hybrids. Was once more widespread, but now lost from much of former range (which included SW New South Wales). Decline a direct result of hybridization with *M. flavigula*. It is thought that, before European settlement, present species occupied dense, continuous and extensive tracts of mature mallee, with *M. flavigula* in more open and fragmented habitats within mallee (e.g. edges and natural clearings, as well as other habitats bordering or within extensive stands of mallee); subsequent broad-scale clearing and provision of watering points and associated modifications resulted in tracts of mallee becoming fragmented, creating much suitable habitat for *M. flavigula* and extensive zones of overlap between the two species; this was followed by widespread hybridization between the two, and genetic swamping of the present species’ population. Wildfire remains a major threat to the survival of this miner, which appears to require mallee vegetation unburnt for at least 45 years; in late 2006, c. 100,000 ha of mallee habitat within Bookmark Biosphere Reserve was burnt. Recovery plan has included translocations of colonies from Bookmark to the Murray-Sunset National Park; five colonies translocated in 2001–2002 have bred, and they persist. A captive-breeding programme is under way, and in 2003 a trial release of 45 captive-bred individuals, in two groups, resulted in breeding in the wild almost immediately and, over following years, establishment of at least three breeding colonies; some birds have joined the remnant wild population at release site.

61. Yellow-throated Miner

Manorina flavigula

French: Méléphage à cou jaune **German:** Gelbstirn-Schwartzvogel **Spanish:** Mielero Goligualdo

Other common names: White-rumped/Yellow Miner; Dusky/Sombre Miner (*obscura*)

Taxonomy. *Myzantha flavigula* Gould, 1840, Namoi River, New South Wales, Australia.

Forms a superspecies with *M. melanocephala* and *M. melanotis*. Often treated as conspecific with latter, and hybridizes extensively with it; analyses of mitochondrial DNA, however, suggest that the two should be treated as separate species. Rarely, hybridizes with *M. melanocephala*. Dark race *obscura* has sometimes been regarded as a separate species. Races intergrade where they meet. Additional proposed races are *clelandi* (from Broome Hill, in S Western Australia), included in *obscura*; *casuarina* (Mt Casuarina, in N Western Australia) and *alligator* (Alligator R, in Northern Territory), both subsumed in *lutea*; and *pallida* (Tietkens Creek, in Musgrave Ranges of C Australia), synonymized with *wayensis*. Five subspecies recognized.

Subspecies and Distribution.

M. f. melvillensis (Mathews, 1912) – Melville I (Northern Territory).

M. f. lutea (Gould, 1840) – N Western Australia (Kimberley Division, including some coastal islands) and N Northern Territory (E to W Arnhem Land) S to eucalypt-acacia transition zone (c. 20° S).

M. f. wayensis (Mathews, 1912) – most of inland Australia from Western Australia and Northern Territory (S of Kimberley Division and Arnhem Land and, in S, NW of inner Wheatbelt) E to Murray–Darling Basin (N of Flinders–Grey Ranges) and S of E Gulf of Carpentaria.

M. f. obscura (Gould, 1841) – SW Western Australia from N Swan Coastal Plain S through inner Wheatbelt to Esperance district (mainly absent from far SW corner).

M. f. flavigula (Gould, 1840) – inland E Australia (W of Great Divide) from Queensland (SE Gulf of Carpentaria and base of Cape York Peninsula E to near Townsville), S to South Australia (S to Flinders Ranges and Adelaide Plains) and NW Victoria.

Descriptive notes. 22–28 cm; 55 g. Nominata race has olive-yellow forehead merging into grey on crown, hindneck and side of neck, with fine whitish scaling on hindneck and side of neck and yellow suffusion on side of neck; black mask bordered below by yellow gape stripe, small patch of bare yellow skin at rear of eye (extending narrowly over and below rear half of eye), small cream spot on rear ear-coverts behind mask; prominent white sub-moustachial stripe, long, narrow orange-yellow bare malar stripe; most of upperbody grey with varying diffuse darker brownish-grey mottling and indistinct fine white scaling, merging over

rump to prominently off-white to greyish-white uppertail-coverts (prominent in flight); tail dark grey, broadly tipped white, rectrices narrowly edged olive-yellow; secondary upperwing-coverts and tertials grey, contrasting with black-brown rest of wing, with fine olive-yellow edges on greater coverts, olive-yellow edges on most remiges (panel on folded wing), and fine white tips on outer primaries; upper chin yellow (visible only with good view), throat and breast off-white to greyish-white, breast with dark grey and white scalloping, diffuse yellow suffusion across upper breast (continuous with that on side of neck); rest of underbody off-white, very pale greyish wash on belly, flanks and thighs; undertail dark grey with white to off-white tip; underwing dark grey, diffuse off-white patch across bases of primaries; iris brown to dark brown; bill yellow to orange, gape slightly paler; legs orange to brownish-orange. Sexes alike in plumage, male larger than female. Juvenile is very like adult, in good view separable by pale pinkish-brown suffusion on crown, neck and upperbody, no white scaling on neck, pinkish-brown wash on tail tip, brown wash across breast (only indistinct scalloping), narrow, indistinct and broken pale pinkish-brown wingbars across tips of median and greater coverts, clearer whitish fringes around tips of outer primaries, and slightly duller yellow bill. Races differ in size, plumage and bare parts: *wayensis* is very similar to nominate but slightly smaller, slightly paler above, with only faint scalloping, paler grey wing-coverts and brown remiges, and paler greyish breast, plumage varies subtly over range, paler inland; *lutea* is larger than nominate, very similar in appearance to previous, but with slightly larger and pale yellow postauricular spot, more extensive yellow suffusion on side of neck and breast, yellow-olive upper lores, paler grey anterior ear-coverts, more prominent bare malar stripe; *melvillensis* is darker and more heavily patterned than preceding races, distinguished from nominate by slightly larger pale yellow postauricular spot (much as in *lutea*), more extensive yellow on side of neck and breast, brownish-grey upperparts more heavily mottled dark brown and diffusely scalloped with light grey, merging across rump into light brownish-grey uppertail-coverts (finely scaled off-white) contrasting much less with rest of upperside, and tip of tail usually washed light brown; *obscura* is darkest, differs from *wayensis* in darker grey upperparts and breast, little or no contrast between rump and rest of underbody, heavier scalloping on breast, narrower pale tail tip, more extensive grey wash below usually covering upper belly (and sometimes more of underbody), darker head pattern with less extensive olive-yellow on forehead, narrower mask with only trace of cream postauricular spot (sometimes absent), shorter and paler moustachial stripe, much darker submoustachial, much darker and uniformly grey throat, no whitish scaling on neck, and smaller and darker olive-yellow patch on side of neck (sometimes absent). **VOICE.** Noisy, but repertoire unstudied. Calls include monosyllabic screams, squeaks and squawks in alarm (apparently identical to those of *M. melanocephala*); rather slow, miaowing “mew-mew-mew”; low guttural “aahh”; melodious chuckle. Tuneful dawn song, heard most often in breeding season, a chorus of whistled notes from members of group. One possibly mimicked a butcherbird (*Cracticus*) call.

Habitat. Nearly all wooded habitats, particularly *Acacia* woodlands and shrublands and open eucalypt woodlands and forests. Commonly in low *Acacia* habitats, e.g. those dominated by mulga or myall (*Acacia papyrocarpa*), usually with understorey of shrubs (e.g. *Eremophila*, *Cassia*, *Grevillea* or chenopods) and ground cover of grasses; and dry open eucalypt woodland, typically with understorey of low shrubs and ground cover of grasses including spinifex (*Triodia*), and riparian woodlands of river red gum (*Eucalyptus camaldulensis*) or coolibah (*Eucalyptus coolabah*); also open eucalypt forests with understorey of tall to low shrubs, including *Banksia*, paperbarks (*Melaleuca*), tea-trees (*Leptospermum*) and casuarinas. Commonly in open tropical sclerophyll woodlands and forests, especially of Darwin woollybutt (*Eucalyptus miniata*) and Darwin stringybark (*Eucalyptus terodonta*), with middle storey of smaller trees including *Erythrophloeum*, *Terminalia*, fern-leaved grevillea (*Grevillea pteridifolia*), paperbarks and *Acacia*, and dense grass layer; and mixed swamp-woodlands of long-fruited bloodwood (*Corymbia polycarpa*), fern-leaved grevillea, yellow-barked paperbark (*Melaleuca nervosa*) and swamp box (*Lophostemon lactiflorus*), or mixed open forests of *Bauhinia*, *Erythrophloeum*, *Atalaya* and eucalypts with tall grass layer; riverine forest of weeping paperbark (*Melaleuca leucadendra*), typically with screw-palms (*Pandanus*) and *Acacia* in understorey. Although rarely in dense mature mallee, found commonly in open regenerating mallee or at edges of mallee and open areas, such as roads and farmland. Often in farmland with scattered trees or remnant patches of native vegetation; sometimes in parks, gardens, orchards and vineyards in towns and homesteads. Also, open woodlands dominated by casuarinas, e.g. belah (*Casuarina cristata*) or buloke (*Allocasuarina luehmannii*), or cypress-pines (*Callitris*);

and chenopod shrublands on plains and lakebeds, and other semi-arid and arid shrublands or thickets. Occasionally in coastal thickets or shrublands dominated by *Banksia*, *Melaleuca* or *Lambertia*, and in or at edges of monsoon rainforests in tropics.

Food and Feeding. Primarily invertebrates, nectar (frequently of *Eucalyptus*), occasionally fruit, e.g. of mistletoe (Loranthaceae), *Rhagodia* and *Copparis*; invertebrates mainly insects, also spiders (Araneae) and pseudoscorpions (Pseudoscorpiones). In South Australia, estimated ratio of insects to nectar in diet 70:30. Forages at all levels, from canopy to ground, occasionally in air. Searches in inner and outer foliage, at flowers, on bark, on herbs, and among stones, leaf litter and dried animal droppings on ground. In Northern Territory, 54% of 119 foraging observations were at flowers, 24% in foliage, 15% on bark, and 7% in air. Nectar taken directly by probing flowers; invertebrates gleaned from vegetation or from ground, or taken by probing into crevices in bark, and under loose bark or debris; occasionally sally-strikes insects in air, and observed also to glean dead insects from cars. On ground, turns over material by probing with bill and lifting head and opening bill wide. Gregarious, noisy and active. Usually in small groups of 5–10 individuals, and adjoining groups sometimes coalesce to form larger flocks of up to 50, exceptionally 100 birds (possibly more often in non-breeding periods); less often in twos (probably pairs), and rarely singly; in the past a flock of more than 1000 individuals noted. Aggressive towards other birds (but said to be less so than *M. melanocephala*), but sometimes associates with other honeyeaters, e.g. seen to feed with *M. melanocephala* on fruits of *Rhagodia*, and fed on ground with *Lichenostomus penicillatus*. In NE Australia recorded in mixed-species feeding flocks with up to ten other meliphagid species.

Breeding. Over entire range recorded in all months, with apparent peak late winter to summer, and concentrated in spring and early summer, most clutches (87%) Aug–Oct; often more than one brood in a season. Nests in loose colonies and breeds co-operatively; suggested that not an obligate co-operative breeder, but breeding attempts by pairs without auxiliaries normally fail. Nest a large deep cup, occasionally a bowl, usually of grass, sticks and wool, often bound with spider web or hair, lined with wool (less frequent materials used in cup include plant stems and rootlets, hair, feathers, flowers, cocoons, bark, leaves, string, cotton thread, fishing line and paper; in lining, grass, rootlets, plant down, flowers, fur and hair, feathers, silky fibre from seed pods, string, cotton, leaves, once lids of trapdoor-spider burrows); external diameter 17.8–20.3 cm, depth 9.5–10.2 cm, internal diameter 7.6–9.5 cm, depth 4.1–7 cm; placed 1.2–1.6 m (mean 4.4 m) above ground, usually in vertical fork amid dense foliage or branchlets of shrub, sapling or small tree, sometimes in coppice growth from middle to upper trunk level of eucalypt, in mistletoe, or close to trunk of tree, sometimes suspended from horizontal limb, once on three upright stalks. Clutch 2–4 eggs, rarely 5 (mean 3.16); incubation by breeding female, very occasionally assisted by breeding male, period c. 15–16 days; chicks fed by three or more birds, probably parents and auxiliaries, nestling period at least 15–16 days, once young appeared to leave nest prematurely at c. 13 days; fledglings fed by at least three individuals. Nests parasitized by Common Koel (*Eudynamis scolopacea*) and Pallid Cuckoo (*Cuculus pallidus*). From 148 eggs in 55 nests at which outcome known, 1.05 young fledged per nest, of 144 nests, 102 (71%) fledged at least one young; nests late in season in semi-arid areas often fail owing to high ambient temperatures.

Movements. Resident. Said to be less sedentary than other miners, with some movements or changes in abundance or occurrence noted. Most changes in numbers probably result of local movements, and may in part reflect dispersal to breed and some post-breeding flocking, e.g. in Victoria discrete colonies sometimes coalesce into larger groups in autumn–winter. Some movements attributed to changes in food availability. Casual visitor at some sites at periphery of range, e.g. records in Broome area (Western Australia) in most months but not every year, and minor influx Jul–Oct 1990. Vagrants occasionally hundreds of kilometres from nearest known populations.

Status and Conservation. Not globally threatened. Common but somewhat patchily distributed, e.g. largely absent from Simpson Desert regions (in C Australia) and from Great Sandy Desert (in N Western Australia). Recorded densities of 0.01–1.4 birds/ha. Range has expanded and populations increased in many regions, chiefly in response to clearance for agriculture (e.g. in Murray–Mallee of inland SE Australia, and in S Western Australia); numbers on Swan Coastal Plain (Western Australia), however, have declined since European settlement. Range expansion in inland SE Australia has resulted in widespread hybridization with *M. melanotis*, to extent that latter species now Endangered. Present species appears to be having similar impact to that of *M. melanocephala* in semi-arid and arid zones, dominating roadside strips or other patches of remnant vegetation and excluding most other small insectivorous birds that would use these corridors or patches. Formerly shot as a pest in orchards and vineyards.

Genus ACANTHAGENYS Gould, 1838

62. Spiny-cheeked Honeyeater

Acanthagenys rufogularis

French: Méléphage à bavette **German:** Braunkehl-Honigfresser **Spanish:** Mielero Golicanelo
Other common names: Spiny-cheeked Wattlebird, Spring-checked Honeyeater

Taxonomy. *Acanthagenys rufogularis* Gould, 1838, New South Wales, Australia.

Genus formerly merged with *Anthochaera* by some authors. Specimen supposedly from an island in Torres Strait described as a geographical race, *parkeri*; locality, however, considered doubtful and specimen probably mislabelled. Monotypic.

Distribution. Australia mainly S of c. 19–20° S (only scattered records in far SW, in S Victoria and E of Great Divide).

Descriptive notes. 22–27 cm; male 39–77 g, female 34–57 g. Plumage is mostly olive-grey above, finely mottled blackish on crown and hindneck and streaked blackish on mantle, back and scapulars,

with dirty-white patch on rump and uppertail-coverts, and blackish tail with obvious narrow white tip; facial pattern distinctive, vivid pink base of bill and gape continuous with vivid pink strip of bare skin extending beneath eye to just behind eye, bordered above by blackish eyestripe and below by bold white cheek-stripe of dense long spiny feathers, cheekstripe broadening down side of neck, where finely streaked blackish, dusky malar stripe with fine whitish streaking anteriorly and becoming broader and darker on side of lower throat; upperwing blackish, white fringes on tertials and median and greater secondary coverts (edges of outer greater coverts tinged yellow-green), fine pale grey edges of primaries, yellow-green edges of secondaries; chin to upper breast pinkish-buff to orange-buff; rest of underbody cream, bold dark brown streaks on lower breast grading finer below (vent unstreaked); undertail black-brown with broad white tip, underwing pinkish-buff to cream-buff with grey-black trailing edge and tip; iris light blue to blue-grey; bill black, base pink; legs black-brown to black. Sexes alike in plumage, male larger than female. Juvenile is similar to adult, but top of head browner, cheekstripe mainly yellow with less bristly texture, underbody slightly duller and with much finer dark streaking, fringes of upperwing-coverts pale buff, and iris brown; immature as adult, but cheekstripe softer and less spiny (often some adult-like feathers admixed), short streak of bright yellow just below and behind gape-line, iris light blue but often with brown inner ring. **VOICE.** Generally noisy, with often reedy and liquid vocalizations; heard throughout day, more in morning. Song, lasting 5–6 seconds, of varied but pleasant liquid whistling phrases, and repeated at intervals; given in flight and while perched, by both sexes. Plaintive but loud, musical, reedy trill, and clear “tok-tok” or “quock” as contact or alarm. Other calls include quiet “click” at intervals during feeding; “taw-tawer” in flight, repeated several times; loud chattering in display-flight, and chuckling notes when dropping back into vegetation after song flight; quiet “cluck” sounds when flushed from nest, and squeaks and squawks during distraction displays. Pairs perform antiphonal duets. Reportedly mimics a range of species, including Grey Shrike-thrush (*Colluricincla harmonica*), Olive-backed Oriole (*Oriolus sagittatus*) and *Anthochaera phrygia*. Snaps bill during chases.

Habitat. Arid and semi-arid shrublands and woodlands, mainly those dominated by *Acacia*, especially mulga (*Acacia aneura*), and often with emu-bush (*Eremophila*) and other shrubs in understorey and grassy ground layer. Also commonly in mallee eucalypt woodlands, shrublands and heathlands, and in mixed acacia–eucalypt associations, often with shrubs (especially *Eremophila*) in understorey; also dry open eucalypt woodlands and forests, especially riparian associations on plains around wetlands or watercourses, such as those dominated by river red gum (*Eucalyptus camaldulensis*), coolibah (*Eucalyptus coolabah*) or black box (*Eucalyptus largiflorens*), with shrubby understorey including *Acacia*, paperbarks (*Melaleuca*), *Myoporum*, chenopods and lignum (*Muehlenbeckia*). Less often in other sclerophyllous habitats, including woodlands of banksias, paperbarks, casuarinas, especially belah (*Casuarina cristata*), or cypress-pine (*Callitris*) or mixed associations of these; or other arid and semi-arid shrublands or heathlands dominated by *Eucalyptus*, casuarinas, *Hakea*, *Banksia*, *Grevillea*, *Dodonaea*, *Geijera*, *Leptospermum* or *Melaleuca*, especially thickets of broombush (*Melaleuca uncinata*) in mallee. Sometimes in heathland; occasionally in wet sclerophyll or mangroves. Sometimes in parks and gardens, vineyards or agricultural land with scattered remnant vegetation.

Food and Feeding. Mainly fruit, nectar and arthropods (mainly insects, some spiders); also seeds; occasionally small vertebrates (including lizards and nestling birds). In one study, ratio of nectar to insects 50:50. Forages mainly in shrubs and trees, among branches and foliage, and on bark; frequently takes nectar and fruit of mistletoes (Loranthaceae) growing on diverse range of plants; sometimes forages on ground or aerially. Probes flowers for nectar, and gleans (plucks) fruits; arthropods obtained by gleaning and sallying, e.g. flying c. 2 m from perch to catch prey and usually returning to same perch. When feeding on fruit of the mistletoe *Amyema preissii*, pecks distal part of fruit to remove some skin, then pecks and swallows exposed fleshy seeds, leaving basal part of skin

attached to stalk, and taking 2–5 seconds to eat single fruit; when feeding on the mistletoe *Lysiana exocarpi*, plucks and swallows fruit whole, taking less than 2 seconds. Usually singly, in twos (possibly pairs) and in small flocks of up to ten individuals; occasionally in larger parties, e.g. up to 100 birds feeding on fruit of *Lysiana exocarpi*. Sometimes associates with other species at food sources. Will defend feeding territories; one appeared to defend territory jointly with *Anthochaera humulata*. **Breeding.** Recorded in all months, eggs in Jun–Mar (75% in late Aug to mid-Nov); in E of range (Queensland S to South Australia and Victoria) eggs Aug–Mar, whereas in W (Western Australia and Northern Territory) eggs mid-Jul to Dec; season possibly prolonged after good rains. Nest a neat, strong but delicate-looking cup, usually of pliant grass, leaves, plant stems and twigs, egg sacs of spiders, plant down and, occasionally, other soft material (e.g. rootlets, flowerheads, feathers), bound with spider web or sometimes wool, lined typically with wool, less often fur, plant down or hair, or other soft material, external diameter 8.9–14 cm, depth 5.1–13 cm, internal diameter 5.5–8.9 cm, depth 4.5–6.5 cm; suspended among branches or twigs 0.8–14 m (mean 2.7 m) above ground, often strongly attached, sometimes with foliage or twigs of nest plant woven into nest, and usually well concealed, generally in live tree or shrub, less often vines or mistletoe. Clutch 2–3 eggs, mean 2.22; role of sexes in incubation of eggs and brooding of young not known; incubation period 14–15 days; chicks fed by both adults, nestling period 14 days to c. 19 days (and recorded as leaving nest prematurely when at least 13 days old); fledglings fed by both adults for at least 12 days. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*). Throughout range 0–65 fledged young per nest; of 100 nests at which outcome known, 57 fledged at least one young and 43 failed. **Movements.** Apparently mainly resident, or present throughout year, over much of range. Possibly partly migratory in some areas, with changes in numbers or occurrence through year, some of which appear seasonal; widely described as nomadic or dispersive in inland regions, although many such reports likely relate to changes associated with local movements. Patterns appear similar in N, C & S parts of range, with no constant differences between regions or latitudes. Some apparent seasonal movements described, e.g. at sites in CS Victoria small numbers regularly spend autumn to early spring away from breeding areas, and possibly undertake some movement to N of range (but also present all year in most such areas, and in some N parts appears to be more common in spring–summer than in winter). Some seasonal occurrence related to flowering, e.g. at one site in mallee heath numbers increased when nectar abundance greatest (Jul–Oct) and low when nectar production lowest (Feb–Jun). Vagrant or sporadic at edge of range; has reached Barrow I, 50 km off Western Australia coast; some vagrant records attributed to drought inland. Occasionally moves in large numbers: in Western Australia, estimated 150 individuals per hour once recorded at Eyre Bird Observatory as part of large movement of birds E along coast (with *Purnella albifrons* and *Anthochaera carunculata*), and 100 or more seen flying SE at Hamelin Pool.

Status and Conservation. Not globally threatened. Rather uncommon to locally common. Densities of up to 0–13 birds/ha in Big Desert (NW Victoria), and 0–07–1–15 birds/ha at Eyre Bird Observatory and 0–006–0–011 birds/ha at L Disappointment (both Western Australia). Claim that a 1883 specimen was from Friday I, in Torres Strait, considered improbable, and specimen thought more likely to have come from Karumba, in NW Queensland; has been suggested, however, that it may have represented an extinct, relict population. Species is adversely affected by clearing of habitat, and may have declined in Wheatbelt of SW Australia. Sometimes considered a pest in vineyards.

Family MELIPHAGIDAE (HONEYEATERS)
SPECIES ACCOUNTS

PLATE 43

Genus *ANTHOCHAERA* Vigors & Horsfield, 1827

63. Little Wattlebird

Anthochaera chrysoptera

French: Méléphage à gouttelettes **German:** Zimtflügel-Honigfresser **Spanish:** Mielerito Alirrojo
Other common names: Brush/Mock Wattlebird, Brush Mockbird, Mock, Mockingbird

Taxonomy. *Merops chrysotus* Latham, 1801. Nova Hollandia = Port Jackson, New South Wales, Australia.

Often considered conspecific with *A. lunulata*. Three subspecies recognized.

Subspecies and Distribution.

A. c. chrysoptera (Latham, 1801) – coastal SE Australia on and E of tablelands of Great Divide from SE Queensland (Dawes Range) S. including Fraser I., Stradbroke I. and other islands, to SE Victoria, and W through SE South Australia to Adelaide.

A. c. halmaturina (Mathews, 1912) – Kangaroo I., off South Australia.

A. c. tasmanica (Mathews, 1912) – N & E Tasmania (and scattered records in SW & W and inland).

Descriptive notes. 27–35 cm; male 57–85 g and female 44–82 g (nominate), male 76–95 g and female 55–63 g (*tasmanica*), male 75–82 g (*halmaturina*). Large, slender honeyeater with long, graduated tail and moderately long and gently decurved bill; no wattles (despite English name). Nominat race has head, neck and upperparts largely dark brown-grey, fine white streaking over top of head merging into longer streaking on hindneck, upper side of neck and upper ear-coverts; prominent cheek-stripe densely streaked silvery white, extending across malar area and lower ear-coverts to side of neck; fine pale spots on lores, chin and

throat; prominent fine white streaks and spots on upperbody, narrow white scalloping on uppertail-coverts; prominent white tip on uppertail; upperwing dark brown-grey, broken white wingbar across tips of median coverts and fine white bar across tips of greater coverts (wingbars lost with wear), broad diffuse grey edges and fine white tips on tertials, diffuse olive panel on secondaries, and fine pale edges and narrow tips on primaries, bases of all except outermost primaries with broad rufous-brown inner edges (in flight, prominent rufous patch in primaries and prominent white tips of outer

primaries); underbody largely brownish-grey, paler than upperparts, fine white streaking on upper breast grading to coarser white streaking and spotting on lower breast, flanks and most of belly, white centre of lower belly and vent faintly washed creamy yellow (stronger in S of range than in N), dark brown undertail-coverts broadly scaled white; also diffuse whitish tuft at side of upper breast (sometimes hidden by folded wing); undertail dark brown-grey with broad white tip; underwing dark brown-grey, broad white scaling across coverts, large rufous patch across base of primaries, and prominent white tips on outer primaries; iris grey, but can change to reddish-brown when bird stressed; bill black (sometimes faintly paler at very tip); legs dark red-brown to black-brown. Sexes alike in plumage, male larger than female (size dimorphism often discernible when partners directly compared). Juvenile is slightly duller and browner than adult, with more diffuse and duller off-white streaking above, buffy (not white) wingbars, off-white streaking (not spots) on chin and throat, duller off-white streaking on breast (and almost no pale streaking elsewhere on underbody), at fledging further distinguished by shorter tail (not fully grown) and small yellowish gape. Races differ only little: *tasmanica* is very like nominate but significantly larger, has top of head to mantle, back and scapulars slightly more olive-toned, belly always washed creamy yellow (but much overlap with nominate), and white tips of outer primaries on average broader; *halmaturina* also is much larger than nominate, from which differs further in distinctly darker, blackish-grey to black-brown, ground colour, and thus white streaking and spotting more contrasting (almost black-and-white appearance), sometimes lacks creamy-yellow suffusion on belly, and olive panel on secondaries diffuse and slightly weaker (but present). VOICE. Noisy, especially in spring–summer, but calls throughout year with typically loud and raucous, harsh, guttural vocalizations. Song loud, harsh and explosive “cooked-apple cooked-apple” or “kok-kra-kwok” or “kok, kok, kra kwok, kra-kwok, kra-kwok” or “wak, wak, keik-keik, keik-kewick”; of wide frequency range and given in bouts of varying duration. Dawn song a prominent feature of dawn chorus, varies geographically: in CE Australia comprised 2 notes of wide frequency combined with single-note, double-note or triple-note calls, whereas at Victor Harbour (South Australia) more musical notes of narrower frequency combined with harsh notes. Other vocalizations include quiet, whimpering, single-note calls during foraging or when close to conspecifics; harsh cackles of 2 or more notes of wide frequency range (1–6 kHz) by lone birds or groups; harsh calls, often from exposed perch for long periods; explosive “kwok”, often with nasal “shairt” in alarm; and agonistic call, consisting of noisy pulses of wide frequency. At one site in non-breeding season, most calls were a repetitive “yekop” and harsh barks, and a repeated sharp “ark” and harsher coughs. Anecdotal reports (possibly referring to some of above calls) also describe short sharp “clock”, given occasionally when foraging; occasional musical notes and high-pitched musical whistles; conversational chucklings and soft calls at nest; and quick nervous call by bird flushed from nest and its mate. Sexes perform antiphonal duets in breeding season, e.g. one calling “kok”, the other answering “kra-kwok”; duets said often to begin with high-pitched metallic shrieks from female, then lower-pitched chuckling squawks from male; may also duet when defending feeding territory. Mimicry noted: one individual associating with *A. carunculata* over four or so days was not heard to give any of its own calls, only those of its congener (though not so loudly). Often rapidly and loudly snaps or clatters bill before or after calling, and loudly snaps bill in aggression towards other species.

Habitat. Mainly sclerophyllous heathlands, shrublands, forests and woodlands, often dominated by *Banksia* or *Leptospermum* or with *Banksia* in understorey: in wet and dry coastal heathlands and mallee heathlands; and dry open sclerophyll forests and woodlands dominated by species such as *Eucalyptus*, *Angophora* or *Banksia* and with dense understorey of sclerophyllous shrubs, often heath, though only occasionally in mallee woodlands. Common in urban gardens, parks and reserves, and in other modified areas such as vineyards and orchards. Occasionally in other habitats, such as coastal wet sclerophyll forest, low coastal casuarina woodland, cypress-pine (*Callitris*) forest, and flowering mangroves. In dry sclerophyll forest in SE Queensland, more abundant in forest with dense understorey of tall and low shrubs and protected from fire than in forest with sparse understorey burnt every 2–5 years or annually. Usually coastal and subcoastal, but extends to tablelands and ranges, especially sandstone ridges, to c. 1000 m.

Food and Feeding. Diet mainly nectar (from wide range of plants but especially *Banksia* and *Eucalyptus*), but also takes manna, fruit, arthropods (especially insects), and insect products (honeydew); recorded also as taking a lizard (*Tiliqua scincoides*). In one study in South Australia, ratio of nectar-feeding to insect-eating estimated at 79:21. Forages mainly in canopy and understorey, very occasionally on ground (e.g. to feed on fallen fruit). Mainly at flowers, probing for nectar, but gleans invertebrates, manna and insect products from foliage, branches and trunks of trees and shrubs; sometimes sallies for flying insects, and sallying can at times comprise large proportion of foraging. In one study in Victoria, of 418 observations of foraging throughout year, 79% involved feeding on nectar, 8% on manna and 13% on insects. Also observed to feed on sap-flows from trees damaged by yellow-bellied gliders (*Petaurus australis*), and seen at beehive and among swarm of bees (Apoidae). In one study in New South Wales c. 8.5% of time spent in foraging, whereas in Victoria spent mean of 42% of time in foraging. Usually forages singly, in twos (probably often pairs) or, less often, in small flocks; occasionally forms large flocks of up to 50–100 birds during autumn–winter at rich sources of food. Will forage with other meliphagid species, including *A. carunculata*, *A. paradoxa* and *Phylidomyris novaehollandiae*. Defends larger feeding territories with higher proportions of flowers than those defended by smaller honeyeaters; at one site, defended feeding territories in areas of abundant nectar, and the trees most used for nectar-foraging were those with most inflorescences.

Breeding. Season mainly spring–summer; eggs recorded in all months, most (58%) early Sept to late Dec; usually two, sometimes three, attempts per season. Usually solitary, but occasionally nests at high densities, and once two nests in one tree; possibly breeds co-operatively at times. Nest normally built by female only, accompanied by male, a shallow open cup or bowl or saucer, sometimes a deeper cup or even roughly domed, reasonably well made of sticks, grass or other plant stems, sometimes with other plant material (e.g. leaves, rootlets, bark, moss), wool, rope or twine or other artificial materials, usually lined with shredded bark, plant down and feathers, less often other soft material, external diameter 7.5–15 cm, depth 7–15 cm, internal diameter c. 7.5 cm, depth c. 3–8 cm; in upright fork, occasionally horizontal or multi-stemmed fork, 0.08–15 m (average 3 m) above ground, usually in small live tree or understorey shrub, occasionally in mistletoes (Loranthaceae), and well concealed among foliage; very occasionally in other site, such as between bark and trunk of tree, and shallow burnt-out hollow of eucalypt. Clutch 1–3 eggs, usually 2 (mean 1.65); roles of sexes in incubation not certain, by both sexes or by female only, male said to feed sitting mate, incubation begins after final egg laid, intermittent, with stints of c. 4 minutes and absences of c. 5 minutes once noted, incubation period 12–15 days; nestlings fed by both parents, sometimes assisted by helpers, nestling period 14–16 days, once 10–12 days (and once, exceptionally, 18 days or more); juveniles fed for 1–3 weeks after fledging, in Tasmania, said that male cares for fledglings while female incubates next clutch. Nests parasitized by Fan-tailed Cuckoo (*Cacomantis flabelliformis*) and Pallid Cuckoo (*Cuculus pallidus*). For 130 eggs in 82 nests, overall breeding success 0.30 fledged young per nest.

Movements. Resident over most of mainland range (nominate race), where present throughout year at most sites, though with local movement. Appears to undertake regular seasonal movements in some areas, and considered migratory or partly migratory at some sites, e.g. mainly autumn–winter visitor at some sites in SE Queensland and South Australia. Seasonal occurrences, however, typically within overall range of apparently resident populations, and distances involved not known; may represent local or regional shifts in population, rather than migration, e.g. individuals at Aireys Inlet (Victoria) make local seasonal movement from eucalypt forest to secluded gulleys in spring. Irregular at and beyond normal range, especially inland of Great Divide and to W of limits of range in South Australia. In Tasmania (*tasmanica*) partly resident and partly dispersive, and often described as nomadic, but little hard evidence of patterns of movements; occurrence erratic at some sites, and sometimes forms conspicuous flocks in autumn–winter; vagrant to King I. Sedentary on Kangaroo I (*halmaturina*), but part of population moves towards coast in spring. Throughout range, movements probably in part influenced by availability of nectar.

Status and Conservation. Not assessed. Probably not globally threatened. Common. No estimates of global numbers; recorded densities of 0.09–0.32 birds/ha. In both mainland Australia and Tasmania, some populations appeared to decline in past, and currently losing natural habitat through extensive development in coastal areas. Populations elsewhere appear to have increased and range expanded, e.g. became established in suburban Melbourne in early 1980s and has since increased in numbers. Increases probably due in part to establishment of native gardens. A minor pest in commercial orchards (stone fruits, pears) in Tasmania. Killed by feral and domestic cats; birds feeding on refined sugar in gardens sometimes die from thiamine deficiency.

64. Western Wattlebird

Anthochaera lunulata

French: Méléphage mineur **German:** Zwerghonigfresser **Spanish:** Mielero Lunulado
Other common names: Brush/Lunulated/Mock Wattlebird, Brush Mockbird, Brush Mockingbird

Taxonomy. *Anthochaera lunulata* Gould, 1838, Swan River, south Western Australia.

Often considered conspecific with *A. chrysoptera*. Monotypic.

Distribution. Coastal and subcoastal SW Australia, roughly S of a line from N Gairdner Range to Hopetoun and E to Cape Arid National Park.

Descriptive notes. Male 29–33 cm, 65–78 g; female 27–30 cm, 47–57 g; unsexed 45.5–83 g. Large, slender honeyeater with long, graduated tail, moderately long, gently decurved bill, and no wattles (despite English name). Head, neck and upperparts are largely dark brownish-grey, with narrow olive-grey scalloping and fine spotting on top and side of head and neck (spotting reduced or lacking with wear); diffuse black-brown eyestripe, pale cheek patch densely streaked silvery white, extending down side of neck; fine white triangular spotting on lower throat; fine white streaks and spots on upperbody, narrow white scaling on uppertail-coverts, and prominent white tip of uppertail; upwearing dark brownish-grey, broken white wingbar across tips of median secondary coverts and fine white bar across tips of greater coverts (wingbars lost with wear), greater coverts also narrowly edged olive, broad and diffuse grey edges and fine white tips on tertials, diffuse olive panel on secondaries, and fine pale edges on primaries, bases of all except outermost primaries rufous-brown on inner webs (in flight, large rufous patch on outer wing); underbody brownish-grey, paler than upperparts, dense fine white streaking and spotting on breast grading to coarser streaking and spotting over side of belly, vent and flanks, with white to creamy centre of lower belly and vent, and broad white scaling on undertail-coverts; also a small white tuft at side of breast (can be hidden by folded wing); undertail dark brownish-grey with bold white tip; underwing dark brownish-grey, broad white scaling across coverts and large rufous patch across bases of primaries; iris crimson to dark red-brown; bill black; legs black-brown. Differs from very similar *A. chrysoptera* in narrower, less bold, white streaks on upperparts and underparts, more triangular streaks on throat, less white on side of throat, no white tips on inner webs of primaries, and longer bill. Sexes alike in plumage, male noticeably larger than female. Juvenile is like adult but duller, browner and slightly paler above and below, with more diffuse and duller, off-white (not white), streaking on upperbody, fine off-white streaking (not white spots) on forehead and crown, distinct buff fringes on greater coverts of upwearing, rounded pale spotting on lower throat, and more diffuse pale streaking on breast. VOICE. Noisy and conspicuous; one of the first species to call in the morning. Calls of female usually higher-pitched than those of male. Most common call a loud croaking “chwaak”, said to be male territorial call. Male also has repeated rhythmic song that begins with clattering “chok” notes mixed with bill-snapping and develops into long, ringing cacklings and chucklings (like those of *Philemon*), repeated often. Other calls include high-pitched twittering, said to be female territorial call; and cheeping “weep” during foraging. Duets common, typically beginning with twitter by female, and include song by male.

Habitat. Mainly open *Eucalyptus*-dominated forests and woodlands with diverse understorey comprising such genera as *Dryandra*, *Banksia* and grass-trees (*Xanthorrhoea*); also in shrublands dominated by *Dryandra* and *Banksia*. Common in city parks with many native trees, uncleared roadside

vegetation, and shelter-belts of non-indigenous eucalypts in farmland. Sometimes in riparian or gully thickets of paperbarks (*Melaleuca*) or saplings.

Food and Feeding. Diet mainly nectar and insects; insects include bugs (Hemiptera) and Hymenoptera, and in one sample mainly ants (Formicidae). At one site, fed on insects more often in Aug–Sept than in May–Jul. In overall time budget in May–Jul, mean of 9.37% of time spent in foraging. Forages mainly in tall shrubs, less often in crowns of trees. Nectar taken from flowers by probing; insects, and probably manna and lerp, gleaned from bark or foliage; also sallies for insects. When foraging for nectar from *Dryandra sessilis*, worked mainly at partly opened (rather than unopened or fully opened) inflorescences; and at *Banksia menziesii* landed on unopened florets at distal end of inflorescence, and leant over to probe most recently opened florets. When foraging for nectar from flowers of *Eucalyptus stoeati*, birds perched or hung from branch near a pendulous flower, and then probed upwards or at an angle through central hole in dome stamens to reach nectar in floral cavity above, sometimes rapidly moving bill in circular motion at base of style. When taking nectar, appears to feed on plants at peak of their production of nectar. At one site, when exploiting flowers of *Dryandra sessilis*, preferred inflorescences 1–2 days old (which produce more nectar than do inflorescences of other ages), and foraged more commonly in large plants, growing in clumps. At inflorescences of *Banksia ilicifolia* (which change colour from yellow to pink to red during maturation), preferred to feed on yellow inflorescences, which had highest nectar content. Usually seen singly, in twos or in small parties, occasionally in flocks of up to 50 individuals; sometimes gathers at sources of abundant food. Often forages with *A. carunculata*. Pugnacious, attacking smaller and larger birds, and will defend nectar sources against other meliphagids, including conspecifics and *Phylidonyris novaehollandiae*; one seen once to defend nectar sources jointly with an individual of *Acanthagenys rufogularis*.

Breeding. Jun–Nov and Feb (late austral winter to summer), with records of eggs Jul, Aug and mid-Feb and of nestlings Jul–Oct. Usually nests solitary. Nest a shallow to rather flat, open cup, moderately well made, of grass, twigs, wool, feathers and occasionally flowers and spider egg sacs, lined with plant down, bark, twigs or grass, external diameter 10.2–15.2 cm, depth 3.8–7.6 cm, internal diameter 6.4 cm, depth 3.2 cm; usually placed in fork of horizontal branch 1.7–15 m (average 3.5 m) above ground in tall shrub or small tree (usually live), sometimes in dense or outer foliage, in vines or in clumps of mistletoe (*Loranthaceae*) growing in shrub. Clutch invariably 1 egg (claims of 2-egg clutches require confirmation), record of three young in nest probably included nestlings of cuckoo (*Cuculidae*); no information on incubation and nestling periods; both parents feed nestling and fledglings. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*).

Movements. Apparently mainly resident, with some local movements. Possibly some seasonal movement towards coast in summer, and inland return in winter and early spring, but few data. Appearance at some sites erratic, but no studies of movements. e.g. occurrence in Eucla Division said to be related to flowering of trees and shrubs, and influx recorded in Darling Range in one year when eucalypts flowering, although numbers fluctuated much. Vagrant at some sites N & E of core range.

Status and Conservation. Not assessed. Probably not globally threatened. Even when treated as specifically distinct from *A. chrysoptera*, does not qualify as a restricted-range species. No estimates of global abundance; recorded densities of c. 0–1.2 birds/ha near Manjimup. Large-scale clearing of native vegetation in Wheatbelt has caused population declines and range contraction; numbers around Perth thought also to have declined in first half of 20th century. In study of effects of logging and burning in karri (*Eucalyptus diversicolor*) forests near Pemberton, found to be most abundant in mature forest, including forest that had not been burnt for at least three years.

Bibliography. Abbott & van Heurck (1985), Arnold (1989), Ashby & Le Souëf (1928), Barrett *et al.* (2003), Blakers *et al.* (1984), Buchanan (1997), Campbell (1900), Carter (1924), Collins & Newland (1986), Collins & Rebelo (1987), Congreve & Congreve (1985), Cooney *et al.* (2006), Ford (1971), Grey (1985), Higgins *et al.* (2001), Hopper (1981), Hopper & Moran (1981), Job (1969), Johnstone & Storr (2004), Keast (1968a), Kitchener *et al.* (1975), Lamont & Collins (1988), Loaring & Serventy (1952), Masters & Milhinch (1974), Mathews (1925), Milligan (1902, 1903), Nichols & Nichols (1984), North (1907), Orton (1918), Ramsay (1989), de Rebeira & Congreve (1982), Recher & Davis (1998), Saunders & Ingram (1995), Schodde & Mason (1999), Schodde & Tidemann (1986), Sedgwick (1940, 1962), Serventy (1948), Serventy & Whittell (1976), Shannon (1984), Storr (1991), Tingay & Tingay (1983), Wardell-Johnson (1984), Wooller (1981).

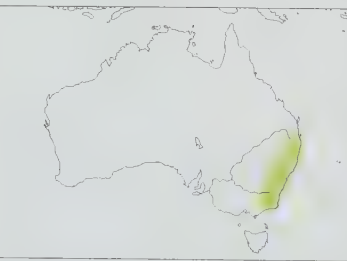

65. Regent Honeyeater

Anthochaera phrygia

French: Méléphage régente **German:** Warzenhonigfresser **Spanish:** Mielero Regente
Other common names: Embroidered/Mock-Regent/Warty-faced Honeyeater, Embroidered Bee-eater/Merops, Mock Regent-bird

Taxonomy. *Merops phrygius* Shaw, 1794, Sydney, New South Wales, Australia. Long placed in a monotypic genus, *Zanthomiza* (often erroneously emended to *Xanthomyza*), but found to be closely related to wattlebirds in current genus. Monotypic.

Distribution. SE Australia from extreme SE Queensland (small numbers in most years) S through New South Wales (mainly on tablelands of Great Divide and N & C inland slopes and plains) to NE Victoria. Throughout range, occasionally reported E or S of Great Divide in coastal and subcoastal districts.

Descriptive notes. 20.4–24 cm; male 41–45.5 g, female 33–45 g. Distinctive, medium-large honeyeater with fairly heavy, decurved bill. Male is mostly black, with large patch of normally dirty yellow (rarely, with pink tinge or dusky pink) bare warty skin on lores and around eye, and bold pale yellow scalloping on upperbody (except upper mantle); upperwing black, pale yellow scaling on coverts, and three bold yellow panels, one on greater primary coverts, one on secondaries and one on outer primaries (in flight, pale yellow on inner webs of primaries also conspicuous); uppertail black with yellow sides and tip (in flight, appears yellow with broad black centre); breast and upper belly black with pale yellow to whitish chevrons, these small and sparse on upper breast and merging into broad and rounded scaling on lower breast and upper belly, which can appear largely pale yellow and finely scalloped black; rest of underbody pale yellow; underwing dark brown to black-brown, with pale yellow fringes of coverts and yellow outer edges at tips of remiges; undertail appears mostly yellow, undertail-coverts covering most of black base; iris dark red-brown; bill black, light grey-brown base of lower mandible, gape black to grey or flesh-coloured; legs dark brown in front, pinkish behind. Female is similar to male but smaller, duller overall, with whole mantle black, upper breast more profusely marked yellow and not so black as male, and yellow of undertail duller; smaller patch of bare skin

on face (still larger than on some young males), slightly shorter and less heavy bill. Juvenile is much duller than adult, dusky brown with small patch of grey to blue-grey bare facial skin (almost smooth, lacking warty texture of adult), cream suffusion on ear-coverts, cream scaling on rump and uppertail-coverts and cream belly and vent merging to pale yellow on undertail-coverts, wing much as adult but ground colour dark brown, and yellow panels duller and less obvious (yellowish-white and smaller on primary coverts, reduced to only one obvious brownish-yellow panel on folded wing), tail as adult but ground colour dark brown and yellow areas duller and often flecked brown, bill initially orange-yellow with brown tip of upper mandible, quickly becoming dark brown, gape orange-yellow and swollen, legs grey-brown; immature like adult female but duller, retains juvenile remiges, rectrices and some upwing-coverts, which strongly contrast with rest of plumage, patch of bare facial skin smaller, smooth (develops warts at c. 9 months of age) and blue-grey, and gape fleshy and yellow at first. Voice. Typically begins calling in morning some 10–15 minutes after most other species. In CE & S New South Wales, very vocal until start of incubation, vocalizing progressively less as nesting progresses; in NE vocalized little during breeding season but called much when in loose flocks in non-breeding periods. Song distinctive, described as a contact vocalization (and uttered often), consisting of soft and penetrating ringing, swelling, slurred syllables, slightly trilled, repeated 2–3 times, sometimes with bubbling quality, and with intricate variation in volume and interval; bill-snaps sometimes included in song. Other vocalizations include: single high-pitched, urgent trill, rising up scale and lasting less than 1 second; meowing, drawn-out single or double note; single-note “plink” or “plink” and variants; quiet bell-like call, consisting of single syllable repeated several times, “ding, ding, ding...” or “whi, whi, whi”; and deep aggressive bark or harsh “chak” when defending roosting site or threatened. Also utters subsong. Mimics calls of larger meliphagid species when associating with them in non-breeding season (utters mimicry also when in non-breeding flocks of conspecifics), and occasionally mimics during breeding season; mimicry usually very close to that of model, but quieter; able to mimic almost whole repertoire of *A. carunculata* and *A. chrysoptera*, also individual calls of *Philemon corniculatus*, *Philemon citreogularis*, Olive-backed Oriole (*Oriolus sagittatus*), Grey Shrike-thrush (*Colluricincla harmonica*) and White-browed Babbler (*Pomatostomus superciliosus*). Bill-snapping during some displays and when chasing.

Habitat. Prefers dry sclerophyll box–ironbark *Eucalyptus* woodlands and forests on inland slopes, especially in moister sites along creeks, river valleys and lower slopes of foothills, and typically dominated by reliable nectar-producing trees including mugga (*Eucalyptus sideroxylon*), yellow box (*Eucalyptus melliodora*), white box (*Eucalyptus albens*) and yellow gum (*Eucalyptus leucoxylon*); also commonly in more open savanna-type woodland of such eucalypt species, or in remnants of such associations in cleared or partly cleared agricultural land. Of 168 observations of habitat across range, 80% were eucalypt woodland or dry sclerophyll forest. Less often in riparian casuarina forests dominated by river sheoak (*Casuarina cunninghamiana*), usually with heavy load of the mistletoe *Amyema cambagei* (and sometimes mixed with eucalypts), and in coastal or subcoastal eucalypt associations, mainly dry sclerophyll forests dominated by swamp mahogany (*Eucalyptus robusta*) and spotted gum (*Eucalyptus maculata*); and more rarely in other coastal associations such as riparian forest dominated by manna gum (*Eucalyptus viminalis*), low open eucalypt forest with heath understorey, or wet sclerophyll forest. Occasionally visits urban parks, gardens and reserves with mature or remnant *Eucalyptus*, and orchards; rarely, riparian shrubland of *Callistemon* and *Leptospermum*, coastal heathland or shrubland, and mallee shrubland. Formerly occurred in dry sclerophyll forest and savanna woodland on ranges and lowland plains in W of range and dominated by combinations of yellow gum, peppermint box (*Eucalyptus odorata*), pink gum (*Eucalyptus fasciculosa*), river red gum and native pine.

Food and Feeding. Predominantly nectar, arthropods (mainly insects), and insect and plant exudates, such as manna, lerp and honeydew; occasionally fruit. Forages mainly among foliage and flowers in crowns of trees, especially *Eucalyptus*, less often at lower levels, including shrub layer, rarely on ground; sometimes on trunks and branches of trees, including beneath bark, or in air. Nectar taken from flowers by probing; insects taken mainly by sallying, but insects, and lerp, honeydew and manna, also gleaned from foliage, from bark of branches and trunks, and from ground. Proportion of time spent in foraging, and proportions in foraging for nectar and in seeking other food items, vary between locations and years: when nectar abundant tends to feed almost solely on flowering species, but when nectar scarce becomes more generalized and forages from a range of tree species and on variety of foods, including lerp and honeydew. From various studies, proportion of time spent in foraging 21–52%, and proportion of foraging time devoted to nectar 6.3–88% and to insects 2–25%; at site where nectar-feeding only 6.3%, much of rest of time (88%) was spent in feeding on lerp and honeydew. At three sites in New South Wales in non-breeding periods, birds spent similar proportions of time in foraging during morning, around midday and in afternoon, except at one site, where significantly less time in afternoon than in other two periods of day. In N New South Wales, in non-breeding season, concentrated on nectar and lerp and honeydew in morning, on insects and lerp and honeydew in middle of day, and on nectar again in afternoon. In breeding season, concentrated on nectar and lerp and honeydew in morning, and mainly on lerp and honeydew (but still with reasonable level of nectar-feeding) in middle of day. In two breeding seasons there was no significant difference in diet between males and females. Conspicuous and aggressive, especially when congregating at food. Active and acrobatic, climbing over thin branches to reach pendulous flowers, and hanging upside-down. Typically gregarious; forages singly, in pairs, or in small to large flocks of 3–50 birds (though individuals in flocks appear to prefer foraging in separate trees); sometimes with other species, e.g. *A. carunculata*. Often defends temporary feeding territories, e.g. one defended territory in flowering stand of mugga from other species, including conspecifics, *Lichenostomus peticillatus*, *A. carunculata* and Musk Lorikeets (*Glossopsitta concinna*).

Breeding. Mainly Sept–Nov but recorded in all months except Apr; in Capertee Valley (CE New South Wales) breeding may begin as early as Jul and continue to as late as Dec (in 1995 laying highly synchronized, in early Oct, but in 1996 and 1997 spread from early Aug to mid-Nov); timing varies significantly between regions in Victoria; seasonal patterns of breeding appear to correspond to regional patterns in flowering of key eucalypt and mistletoe species, and breeding effort also varies significantly between years; reneating after success or failure observed, but apparently not common. Nests as simple pair, partners remaining together for at least one season. Solitary or in small loose colonies or groupings; regularly colonial in Capertee Valley, possibly because population density greater than elsewhere. Female collects material and builds nest, male staying nearby, rarely both sexes collect material and build, work taking 4–9 days; nest an open, rounded, thick-walled cup made of combinations of strips or flakes of soft bark, coarse dry grass, casuarina needles or a few fine twigs, bound with spider web and sometimes cocoons, lined with fine material such as bark shreds, grass, rootlets, wool and hair, external diameter 10.1–12.7 cm, depth 5–6.4 cm, internal diameter 6.4 cm, depth 3.2–5 cm; placed 1–30 m (averages in different studies 11–14.5 m) above ground, usually in vertical fork or on horizontal or angled branch, sometimes supported by vertical twigs, typically in foliage close to edge of canopy (most commonly a near-horizontal limb where two or three smaller vertical branches shoot off), in crown of tall tree (mostly eucalypt or casuarina), sometimes in mistletoes, sometimes close to ground in sapling or shrub, occasionally in artificial site such as top of fence post or rafter of open shed; once built in

old mud nest of Magpie-lark (*Grallina cyanoleuca*). Clutch usually 2 eggs, sometimes 3, mean in New South Wales (Capertee Valley) 2.2; incubation by female only, at one site sitting for average of 65% of daytime (average 5.5 bouts per hour), incubation period 12–15 days (mean 14 days); chicks brooded by female, fed by both sexes at about equal rates, male sometimes contributing more, nestling period 13–17 days (mean c. 16 days), but up to 21 days in wet weather; both sexes also feed fledglings, juveniles partly independent 2 weeks after leaving nest and fully independent c. 1 week later, or fully independent on average 27.6 days after fledging.

Movements. Movements complex, poorly understood, and apparently largely governed by flowering of *Eucalyptus* species that produce large volumes of nectar. Suggested that this species may combine seasonal movements between regions with local movements. Detailed analyses reveal three main trends: movement into parts of N New South Wales and SE Queensland (formerly, also South Australia) in autumn, with contraction into core breeding areas on inland slopes of Great Divide in NW, CW & SW New South Wales in late winter and in NE Victoria in middle to late autumn; a corresponding movement out of S Victoria and highlands of SE Australia from late autumn to early spring; and regular use of sites with predictable annual peaks in nectar production. Recorded as leaving sites or moving with *Philemon corniculatus*. Most ringing recoveries or resightings are close to site of ringing, but some long-distance movements recorded, e.g. two adult males breeding at Canberra in Dec 1995 were resighted in Capertee Valley (258–269 km N) in Oct 1997 and Mar 1998 (one bred at both sites), and one adult moved 176 km in maximum of 20 days. Young may also disperse some distance, e.g. two nestlings and an adult male resighted 20 km NW of ringing site 19 days after young fledged, and one colour-ringed nestling that fledged in late Nov was recaptured 17 days later (and still being fed by parents) 3.4 km away. A few records beyond normal range, e.g. singletons near Eulo, in SW Queensland, Aug 1980, and at Mystic Park, in NW Victoria, Oct 1979.

Status and Conservation. ENDANGERED. Total population estimated at 500–1500 individuals, within range smaller than 300,000 km². Thought to have a small and highly mobile population, and appears to have declined markedly and continues to do so. Formerly widespread in E & S Australia but range and numbers have contracted greatly, mainly as a result of loss, fragmentation and degradation of habitat. Declines probably began in c. 1940s, mainly following clearance and fragmentation of preferred high-quality habitat for agricultural purposes; degradation of remaining habitat through increased dieback and decline of trees in pastoral areas, lack of regeneration of *Eucalyptus* owing to grazing by livestock and rabbits (*Oryctolagus cuniculus*), and silvicultural practices that promote dense pole regrowth of immature trees and remove large spreading trees, and removal of trees for fence posts, firewood and timber. Estimated c. 75% of original habitat has been cleared, particularly lowland habitat on most fertile and productive sites, resulting in poorer and unreliable supplies of nectar. Remnants, including much of what currently exists in the conservation reserve system, are highly fragmented and often degraded. Further, loss and degradation of habitat may have facilitated expansion of large aggressive honeyeaters, such as *Philemon* and *Manorina*, possibly resulting in interference with present species at food sources and nesting sites. In 19th century was recorded in large numbers, occasionally in very large flocks (even of thousands) during influxes. Very few current records of large flocks, e.g. largest one noted 1977–1985 was of 37 birds; and in New South Wales and Victoria, 1988–1990, 61% of observations were of 1–2 birds, and largest flock of 23 birds; larger flocks (32–151 birds) recorded 1994–1997. Range has also contracted, e.g. formerly recorded farther N in Queensland. In New South Wales, recorded less often and in smaller numbers than previously, although overall range appears not to have contracted greatly, but apparently now absent from Riverina. In Victoria, less common or vagrant in several regions where formerly regular, including coastal E & S Gippsland and parts of SC Victoria; not recorded around Bendigo (where formerly common) or W of there since late 1980s. Probably extinct in South Australia; last recorded in 1977 but formerly widespread and abundant in S, with most records around Adelaide and in Mt Lofty Ranges. Formerly caused much damage to orchards during irruptions. Recent conservation efforts focused on protecting and restoring habitat at sites regularly used by the species. Also, captive-breeding has produced some success: in 2008, 27 individuals of this species (all fitted with radio transmitters) were released in Chiltern National Park, in Victoria, and very soon thereafter one was observed next to a wild individual, the first seen in the park for 18 months.

Bibliography. Allan (1989), Anon. 66. Red Wattlebird

Anthochaera carunculata

French: Méléphage barbe-rouge **Spanish:** Mielero Carunculado
German: Rotlappen-Honigfresser
Other common names: (Common) Wattlebird, Wattled Honeyeater

Taxonomy. *Merops carunculata* Shaw, 1790, region of Port Jackson, Sydney, New South Wales, Australia.

May form a superspecies with *A. paradoxa*. Nominate race and *woodwardi* intergrade in broad zone across SE South Australia and W Victoria. Three subspecies recognized.

Subspecies and Distribution.

A. c. woodwardi Mathews, 1912 – S Western Australia E to S South Australia (E to Mt Lofty Ranges).

A. c. carunculata (Shaw, 1790) – SE Queensland S (mainly on and E of Great Divide) to Victoria and SE South Australia (W to about Mt Lofty Ranges).

A. c. clelandi (Mathews, 1923) – Kangaroo I, off South Australia.

Descriptive notes. Male 33–37 cm, 90–140 g; female 34–37 g, 82–133 g. Nominate race has head and neck black-brown, densely streaked white on nape and hindneck, uniformly dark cap bordered below by silvery white facial patch, this in turn edged below with bold black-brown submoustachial stripe that curves up behind ear-coverts (narrow strip of pink skin sometimes visible in front of black border of rear ear-coverts), and with fairly large reddish wattle hanging from lower rear ear-coverts and whitish line down side of neck from behind ear-coverts; chin and throat white, coarsely

and vent; undertail brownish-grey with bold white tip; underwing brownish-grey, scaled and mottled white on coverts, pinkish-buff bases and white tips on primaries; iris red; bill black, gape grey-black; legs pink-brown or pink. Sexes alike in plumage, female usually slightly smaller than male. Juvenile is like adult but slightly duller and browner, with fine white streaks on duller brown cap, finer white streaking on body, usually smaller and paler yellow patch below, fringes of coverts and remiges pink-buff at first (soon fading to adult appearance), submoustachial stripe as adult or silvery white and bordered by thin dark moustachial and malar stripes, iris dark brown, bill duller with tiny pale tip, puffy yellow-orange gape, wattle much smaller and paler, legs much brighter pink, strip of bare skin at rear of ear-coverts duller pink. Race *woodwardi* is like nominate but slightly smaller (wing of male significantly shorter), slightly richer yellow on belly; *clelandi* is similar in size to nominate (but male bill significantly longer and tarsus shorter), slightly darker overall (dusky feathering even on cheek patch), but some adults identical in plumage to some nominate. **VOICE.** Range of loud, harsh, raucous vocalizations; particularly noisy when congregating at food source. Calls throughout year, most often in spring or during breeding; often calls when flying from tree to tree. Common vocalizations include: loud, raucous and guttural cackle or coughing consisting of series of notes of wide frequency range, usually with emphasis on final note, "yak, yaak, yakyak" and "yakayak", usually (or only) by male, when foraging alone, during communal gatherings or in territorial encounters; varying series of rapidly repeated single whistled notes, "pleu, pleu, pleu..." or "tew-tew-tew-tew", 3–4 times per second, usually by female; emphatic single note, sounding like "cook", "chock" or "quok", some harsh and raucous, others with more harmonic structure, thought to be contact call. Other calls include: both narrow-band and broad-band alarm calls used alternately when mobbing a predator, narrow-band ones a rapid succession of low-pitched pulses with narrow frequency range, and broad-band ones loud, harsh and rasping with wide frequency range; harsh distress calls when handled; harsh call similar to broad-band alarm, given during agonistic encounters with conspecifics or other species; soft clucking call sometimes given when approaching nest with food, or when about to feed young; chatter by both members of pair before chasing each other in flight. Pair-members appear to duet, female giving whistle while male gives cackle; also, when partners meet at foraging site where other birds present, female often gives whistle in reply to male's cackle. Sometimes snaps bill in aggressive circumstances or when bathing.

Habitat. Wide variety of dry to moist sclerophyllous forests and woodlands, usually dominated by *Eucalyptus*, with understorey of grass or sclerophyllous shrubs; also in remnants of these associations in agricultural land, though recorded also in healthy forests and woodlands more often than in those affected by dieback. Sometimes in wet sclerophyll forest, e.g. mature stands or regrowth of mountain ash (*Eucalyptus regnans*) and alpine ash (*Eucalyptus delegatensis*) with rainforest or sclerophyllous understorey; and in mallee and coastal shrublands and heathlands, and thickets of broombush (*Melaleuca uncinata*) in mallee. Common in urban and rural parks and gardens, on golf courses, and sometimes in vineyards and orchards. Very occasionally in other habitats, e.g. riparian paperbarks (*Melaleuca*), riparian casuarina forest with much mistletoe (*Loranthaceae*), cool and warm temperate rainforest, exotic pine (*Pinus*) plantations, acacia or cypress-pine (*Callitris*) woodland or shrubland; also high-altitude herbfield or alpine heathland during snow-free months. In karri (*Eucalyptus diversicolor*) forests in SW Australia most abundant in mature forest, including forest not burnt for at least three years. Sea-level to c. 1900 m.

Food and Feeding. Diet mainly nectar, also invertebrates (mainly insects), lerp, honeydew and manna, and fruit; rarely, small reptiles (Scincidae) and eggs and nestlings of small birds. Proportions of main categories and methods of foraging vary. Ratio of nectar-feeding to insect-eating in one study 67:33. Forages from upper canopy to understorey, in air, and occasionally on ground. Obtains nectar by probing flowers (sometimes while standing on ground) of wide range of trees and shrubs, especially those that produce large volumes of nectar (including *Eucalyptus*, *Banksia*, *Eremophila* and *Xanthorrhoea*). Invertebrates taken mostly by probing bark and sallying (sometimes for long distances), but these and lerp, manna and honeydew also gleaned from bark and foliage or other substrates. Also pounces from low shrubs on to insects, and searches from ground and then hops to attack prey. Readily eats soft fruits, such as peaches, figs and plums, in orchards. Seen to feed on sap exuding from scars on *Eucalyptus* trees gouged by sugar gliders (*Petaurus breviceps*). Will feed at artificial feeding stations. Active, noisy, aggressive and conspicuous, but can be quiet and wary at times; clambers among branches, and often stretches and hangs to reach flowers. In C Victoria, two phases of foraging activity: one in early morning, with high levels of nectar-feeding and little insectivory, and a second over rest of day, with reduced nectar-feeding and increased insectivory (switch between the two usually in mid-morning). Forages singly, in pairs or in small groups; occasionally in large flocks of up to 100 or more individuals on Kangaroo I. Associates with many species at food sources, especially other meliphagids, including *Phylidomyris novaehollandiae*, *Philemon corniculatus*, *Philemon citreogularis*, *A. lunulata* and *A. chrysoptera*, and lorikeets (of genera *Trichoglossus* and *Glossopsitta*). Often defends feeding territories, either solitary or in pairs, from other nectarivorous birds.

Breeding. Eggs late May to Jan (mostly early Sept to early Nov) and breeding noted in all months except Apr and early May; at Imbota (in N New South Wales) first eggs Aug and last fledglings Feb, and 90% of 105 nests in Sept–Nov; probably normally double-brooded, and sometimes three attempts in a season. Solitary, but occasionally communal nester. Apparent co-operative breeding observed occasionally. Nest built by both sexes, sometimes by female only, work can take 2 weeks or more, large but varying in shape, from almost flat or saucer-shaped to deep open cup (possibly flattened during nesting attempt), in E Australia consists of three parts, a concave substructure of long thin sticks or grasses, a cup of smaller sticks, bark or grass in hollow of substructure, and a soft lining usually of bark but also of wool or fur, fine grasses, plant down, feathers, occasionally rootlets, small twigs or spider web (in W Australia, nest typically unlined), other materials used in nest include leaves, plant stems, or string, external diameter 15–23 cm (in W Australia, two nests 80 cm across), depth 9.5–12.5 cm, internal diameter 8.9–10.2 cm, depth 5.1–6.2 cm; placed 0.33–30 m (mean 6.4 m) above ground, usually supported by horizontal or sloping branch, vertical fork or branchlets in tall live shrub or tree (especially *Eucalyptus*), or in mistletoe (29% of nests in Imbota); twice built in old nest of Magpie-lark (*Grallina cyanoleuca*). Clutch 2 eggs, occasionally 1 or 3,

mean for whole range 1-97; incubation by both sexes or by female only, possibly from laying of first egg, period 16–21 days, once 15 days; chicks brooded by both sexes, mostly by female, fed by both about equally, immatures (assumed from previous brood) occasionally make small contribution to feeding of young; nestling period estimated at 15–20 days, but once 14 days and once 26 days (and in four other nests more than 20 days), period may be extended in cold, wet weather; fledglings fed by both parents, typically for 2–3 weeks after leaving nest, adult observed to be incubating clutch while fledglings of previous attempt still being fed. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*) and, less often, by Common Koel (*Eudynamis scolopacea*). For 272 eggs in 143 nests throughout range, overall success 0.51 fledged young per nest; of 90 nests over eight seasons in Imbota, 33.3% fledged at least one young; many nests probably fail in poor weather.

Movements. Complex and few clear patterns. At least partly seasonal and partly migratory. At study sites on Great Divide and on coast of New South Wales, no seasonal trends and no evidence of long-distance N–S movement. Considered resident (or recorded all year) at many sites throughout range, but movements (or, at least, changes in numbers or presence) also reported throughout range, and even where present all year numbers may fluctuate. At several locations, resident populations augmented by non-breeding visitors or passage migrants. Often described as nomadic or partly nomadic, usually on basis only of presence/absence at sites and with no study or evidence of genuine movement; where considered erratic or nomadic extent of movements involved unknown, and may be largely local. Considered partial N–S migrant in Western Australia and possibly in S coastal New South Wales, but migration routes not properly known; birds moving annually through coastal New South Wales possibly include individuals from Victoria. Altitudinal migration from areas above 1500 m in highlands of SE in autumn–winter. Some evidence of autumn–winter movement inland in E & S of range. Records outside normal range usually in winter. Many local or regional movements may be response to flowering of foodplants. Sometimes apparent passage observed (e.g. hundreds moving along ridgetops) and recorded with large numbers of *Lichenostomus chrysops* and *Meliphreptus lunatus*. Nominate race vagrant in New Zealand: two records North I (at Matakana c. 1865; and Rohutu, Taranaki, c. 1885), and unverified report at Motupiko before 1938. **Status and Conservation.** Not globally threatened. Locally common. Many estimates of density, ranging up to 3 birds/ha. Local or regional populations adversely affected by loss or degradation of habitat, e.g. in Wheatbelt of SW Australia has declined or disappeared in areas that have been widely cleared. Conversely, common in some urban areas and thought to have benefited from establishment of urban gardens. Formerly shot in large numbers, for sport and for food; also because considered a pest in orchards and vineyards, although true extent of damage probably low. Often killed by feral and domestic cats, and sometimes killed in collisions with vehicles or when flying against house windows. Can die from thiamine deficiency when fed on refined sugar in gardens.

67. Yellow Wattlebird

Anthochaera paradoxa

French: Méliphage à pendeloques

Spanish: Mielero Ventriamarillo

German: Gelblappen-Honigfresser

Other common names: Tasmanian/Long Wattlebird, Great-wattled Honeyeater

Taxonomy. *Corvus paradoxus* Daudin, 1800, Nouvelle Zélande; error = south-east Tasmania, Australia. May form a superspecies with *A. carunculata*. Two subspecies recognized.

Subspecies and Distribution.

A. p. kingi (Mathews, 1925) – King I, in Bass Strait.

A. p. paradoxa (Daudin, 1800) – C & E Tasmania.

Descriptive notes. Male 44–50 cm, 135–260 g; female 37–43 cm, 104–190 g. Largest honeyeater, with long, graduated tail. Nominate race has face, chin and throat largely white, contrasting strongly with white-streaked blackish-brown cap and hindneck; diffuse dusky grey loreal stripe, diffuse dark grey moustachial stripe, long (up to 6 cm) pendulous yellow to orange-yellow wattle dangling from rear ear-coverts, and narrow dark grey malar stripe that broadens along side of throat and merges with grey-black side of neck behind wattle (wattle varies seasonally: white basally, grading to yellow on distal third or so, but in breeding season engorged and brighter yellow, grading to orange-yellow or orange at tip); most of lower side of neck whitish, finely streaked brown; upperbody dark brown with fine pale grey-brown streaking and (in fresh plumage) fine greyish scaling; uppertail dark brown, washed

grey in centre, with bold white tip; upperwing dark brown, fine white tips on median secondary coverts and narrow white fringes on greater coverts, broad diffuse pale grey fringes on tertials, and fine pale grey edges on remiges broadest on secondaries (prominent pale panel on folded wing), white tips on primaries (prominent in flight); underbody mostly white, fine dark brown streaking in middle of upper breast merging into coarser dark brown streaking over rest of breast and fore-flanks, and to more diffuse and paler grey-brown streaking on rest of underbody, with large yellow to orange-yellow patch on belly; undertail dark brownish-grey with bold white tip; underwing dark brownish-grey, white scaling on coverts, pale buff patch across bases of primaries; iris black-brown (conspicuous in pale face); bill black; legs pink-brown to dull pink. Sexes alike in plumage, male much larger than female. Juvenile is plainer and browner than adult, top of head to neck and upperbody uniformly light brown, finely streaked off-white, dusky loreal, moustachial and malar stripes less distinct, wattle rudimentary, upperwing with bolder white streaks on marginal secondary coverts, buff fringes on median coverts, and duller buff-white tips on primaries, chin and upper throat off-white, light grey lower throat merging to uniformly light brown breast, rest of underbody cream with light brown wash on flanks, smaller and paler yellow belly patch, gape yellow-orange, iris paler than adult; immature separable from adult for short period after post-juvenile moult by combination of adult-like plumage and small wattles (much as on juvenile), inseparable when wattles approach full length (within 6 months of fledging). Race *kingi* is similar in size to nominate but slightly duller, with slightly greyer crown to upper mantle, brown back more distinctly streaked, pale fringes of tertials and secondaries finer and white tips of remiges and tail narrower, breast slightly browner, yellow belly patch smaller and paler (lacking orange tinge), wattles finer. Voice. Noisy, especially foraging flocks, and calls audible over some distance, but vocalizations poorly known. Starts calling at first light. Calls loud, harsh and guttural, comprising discordant coughing “kuk”, “wok”, “quok”, “cagh”, “ca-wok” or “ku-kuk”; or single notes in series interspersed with guttural, gargling-like notes. Also a harsh and discordant alarm call. Partners appear to duet, gargling or gurgling notes by female interspersed with harsh croaks from male.

Habitat. Mainly *Eucalyptus*-dominated sclerophyll forests and woodlands, particularly dry sclerophyll forest, preferring unburnt or mature forest, especially with dry understorey of grasses or sedges and with *Banksia* in middle storey. Also wet sclerophyll forest, e.g. dominated by mountain ash (*Eucalyptus regnans*) or alpine ash (*Eucalyptus delegatensis*) with understorey of either sclerophyllous vegetation or cool temperate rainforest; also open eucalypt woodland (sometimes with heathy understorey); and subalpine forest, usually with diverse shrub layer. More rarely, in closed, shrubby dwarf coniferous forest above subalpine zone. Common also in urban parks and gardens and other open spaces with some trees (such as golf courses), and orchards. Less often in cool temperate rainforest of Antarctic beech (*Nothofagus cunninghamii*), or coastal or inland heathland or shrubland; a few records in low open habitats, such as sedge-lands of button grass (*Gymnoschoenus sphaerocephalus*), snow grass (*Poa*) or perching lily (*Astelia alpine*). Sea-level to c. 1350 m, mostly below 1000 m.

Food and Feeding. Nectar (mainly from *Eucalyptus* and *Banksia*); some arthropods (insects and spiders) and fruit. Forages at all levels, from crowns to shrub layer near ground, and occasionally on ground, but mainly in canopy more than 10 m above ground; mostly at flowers or among foliage, but also on small and large branches and trunks of trees, including under loose bark. Nectar obtained by probing flowers; invertebrates gleaned from foliage, branches and trunks, or taken from beneath bark by probing or after pulling off strips of bark; occasionally sallies for insects or feeds at sap-flows of eucalypts. Visits gardens and orchards to feed at flowers or for fruit; usually takes over-ripe or fallen fruit, but sometimes eats ripe fruit. Active, conspicuous and aggressive. Singly, in twos (probably pairs), and in small to large flocks of up to 40 individuals, latter sometimes forming at sources of abundant food; sometimes with *A. chrysoptera* or other honeyeaters.

Breeding. Season Aug–Jan, laying Sept–Nov, and dependent fledglings noted Oct and Jan; season later in Central Highlands than on coast; often two broods in coastal regions. Nests as solitary pairs. Nest built by female, male sometimes carrying material, varies from rather flat and open bowl to a shallow to deep but substantial cup, made of thin sticks and bark, sometimes with grass, wool, rootlets, feathers or leaves included, lined with fine bark, rootlets and grass, feathers, paper, wool or marsupial fur, external diameter 18–25 cm, depth c. 8 cm; placed 4.5–45 m (usually 3–20 m, mean 18 m) above ground, often in partly exposed position, usually in vertical (less often horizontal) fork of live tree (mostly *Eucalyptus*) or shrub, sometimes on branch, top of stump, in niche in side of tree, or suspended among foliage or epicormic growth. Clutch typically 2 or 3 eggs, but records of single egg (clutch size not known with certainty); incubation probably by female, male possibly taking smaller share of duties, beginning on evening after second egg laid, period 14–16 days, possibly as short as 12 days; chicks brooded and fed by both parents, nestling period 18–21 days; fledglings fed by both parents, dependent for up to several weeks. Often only one young raised from brood of two, or two from three.

Movements. Not properly understood. Most movements appear erratic, especially in non-breeding periods; sometimes linked with local flowering of plants, especially *Eucalyptus*. Apparently sedentary in some areas, with stable numbers throughout year, or part of population appears to undertake regular seasonal movements. Altitudinal shifts in some areas, e.g. increased records at some higher-lying sites in late summer and early autumn, or movement to foothills and plains during winter and away in spring; tends to visit suburban gardens more often in autumn–winter. Autumn–winter flocks commonly reported, but not known whether these represent general altitudinal shift or other movements. Irruption of “hundreds of thousands” reported around Riversdale, on E coast, in winter 1894. Occasional records outside normal range, e.g. in W & SW, and on Three Hummock I and Hunter I (off NW coast); historical report from Furneaux Group considered doubtful; unconfirmed report S mainland Australia (Victoria).

Status and Conservation. Not globally threatened. Restricted-range species: present in Tasmania EBA. King I race (*kingi*) “vulnerable”: adversely affected by clearance of habitat, but population there probably stable, although thought to number fewer than 1000 mature adults. Nominate race locally common, recorded densities of 0.08–0.53 birds/ha (near Woodsdale), and 0.25–0.99 birds/ha (near Campbell Town); numbers thought to have declined up to 1950s, possibly as a result of hunting. Prefers older stands of dry sclerophyll forest, with densities significantly higher in mature forest than in younger regrowth; similarly, appears to prefer unburnt forest. Was formerly legally shot during an open season (May–Jul), the most recent of which was in 1972; often eaten, and sold in markets. So many were killed in early years that species was thought to be in danger of extinction, and was fully protected in 1902–1903, but was later legally hunted again.

Bibliography. Ashby (1925), Barrett *et al.* (2003), Blakers *et al.* (1984), Campbell (1900), Fielding (1977, 1979), Fletcher (1910, 1911, 1924), Gannon (1962), Garnett & Crowley (2000), Green (1969, 1989, 1995), Green & McGarvie (1971), Griffioen & Clarke (2002), Harris (1980), Henderson & Green (1982), Higgins *et al.* (2001), Hingston (1994), Keast (1968a), Le Souëf (1902b), Littler (1903a, 1903b, 1910), Mathews (1925), McGarvie & Templeton (1974), Mellor (1907), Napier (1967, 1969), North (1907), Ratkowsky (1979, 1983, 1993a, 1993b), Ratkowsky & Ratkowsky (1977, 1980), Recher *et al.* (1971), Ridpath & Moreau (1966), Rose (1980), Rounsevell *et al.* (1977), Schodde & Tidemann (1986), Sharland (1925, 1944, 1958), Slater (1994), Taylor *et al.* (1997), Thomas (1972, 1979, 1986), White (1985), Wilson (1950).

Genus *RAMSAYORNIS* Mathews, 1912

68. Brown-backed Honeyeater

Ramsayornis modestus

French: Méliphage modeste **German:** Sumpfhonigfresser **Spanish:** Mielero Modesto
Other common names: Modest/Unadorned Honeyeater

Taxonomy. *Glyciphila modesta* G. R. Gray, 1858, Aru Islands. Suggestions that populations from NE Australia are intermediate between present species and *R. fasciatus* are not supported by any studies. Monotypic.

Distribution. West Papuan Is (Waigoe, Batanta, Salawati); Aru Is; coastal S & SE New Guinea, and also very locally in W Vogelkop (Sorong) and along N coast, with isolated records at Mamberamo R, Wewak and Madang; D'Entrecasteaux Archipelago (Goodenough I, Fergusson I); islands of N Torres Strait (including Boigu, Saibai, Daru and Yam); and NE Australia (Cape York Peninsula S to about Aurukun on W coast, and along E coast S to Bowen, with occasional records on islands off E coast).

Descriptive notes. 12–13 cm; male 11–14 g, female 8–5 g. Rather drab, small and plump honeyeater with short tail. Plumage is mostly brown above and white below, with blackish-brown mottling on forehead and crown, diffuse dark loreal stripe, narrow white facial stripe from bill to below and just behind eye bordered below by thin brown moustachial stripe; off-white area of malar, chin and throat extending in notch up behind ear-coverts (in fresh plumage, ear-coverts finely frosted with white barring); upperwing and upperpart dark brown, fine paler brown fringes on secondary coverts and tertials, paler brown edges on remiges and rectrices (edges of secondaries forming diffuse pale stripe on folded wing); faint and diffuse light brown barring across breast merging into diffuse streaking along flanks; undertail dark grey, underwing pale buff with dark grey trailing edge and tip; iris deep red-brown; bill wholly dirty pink or with dusky upper mandible; legs dirty pink. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but no dusky mottling on top of head (some have fine brown barring in white facial stripe), has brown on side of breast merging into gorget of diffuse brown streaking (not barring) that continues along flanks, median and greater upperwing-coverts have slightly broader and buff fringes, tertials fringed buff and rest of remiges edged buff, also bill blackish-brown with dirty pink base of lower mandible, gape yellow, and legs like adult or grey-black. **VOICE.** Commonly heard. In New Guinea, song a series of short chirping notes interspersed with soft twittering, or repeated sharp “chit”. Other calls include “mick-mick-mick” or dry “chip” often given in flight; low chirping notes; soft chattering “shee-shee-shee...”; dry “chh chh”, second note slightly higher; repeated faint dry notes or high squeaky notes, all on same pitch; and sharp, shrill monotonous cry, repeated at intervals.

Habitat. In Australia mainly riparian paperbark (*Melaleuca*) thickets or woodlands surrounding ephemeral wetlands, also in adjacent open riparian forest or woodland dominated by *Eucalyptus* or paperbarks, often along watercourses, or gallery rainforest on creek-lines; sometimes in mangroves and in urban gardens and parks. In New Guinea commonly in mangroves, savanna eucalypt woodland, or riparian paperbark thickets, woodlands or forest around swamps or on islands in lakes, including lowland paperbark forest mixed with palms and *Terminalia* at lake edges; occasionally in forest-scrub, coconut plantations, town gardens, roadside vegetation, and recorded also in patches of reeds in floodplain of Middle Fly R. Lowlands, to 600 m.

Food and Feeding. Mainly nectar and insects. Forages in foliage, at flowers and on branches of trees, mostly paperbarks. Nectar taken by probing flowers; insects gleaned from foliage and branches of trees or caught in sally-strike and sally-hover. Conspicuous; flits actively about in vegetation. Usually in twos (probably pairs), less often singly; occasionally in small flocks of up to 18 individuals, especially in flowering trees; in New Guinea in Apr. often in parties of 3–4, possibly family groups. Seen to forage with *Melithreptus gularis*, and in New Guinea often in flowering trees with lorikeets (*Trichoglossus*) and *Myzomela obscura*.

Breeding. In Australia reported in all months except Jun, and eggs recorded mainly Sept–Oct; in New Guinea recorded in all months, mainly Aug–Nov, with eggs and nestlings Sept–Nov, nestlings Apr and fledglings Jan–Feb and Apr. Nests in small groups or colonies (e.g. 21 nests within radius of c. 50 m), also solitary (e.g. mean 42–82 m between nests); clustering possibly related to habitat. Nest built by both sexes, although one in New Guinea built by female alone, a bulky, elongated, pendulous dome, side entrance near top and usually hooded, usually made of strips of paperbark, bound with spider web and cocoons, lined with soft pieces of paperbark, some nests made of grass, bark and leaves and lined with feathers or apparently unlined, external length 13–24 cm, diameter 7–11 cm, internal length 5–11 cm, diameter 4–5 cm, entrance diameter 2.5–6.5 cm; suspended in outer twigs of tree, often above water but can be well away from water, 0.6–16 m (mean 4 m) above ground, 57 nests in Townsville (Queensland) 1–8 m (mean 2.7 m), in New Guinea 1–10 m. Clutch 1–3 eggs, usually 2 (mean 2.09); incubation apparently by female only, period 14–16 days; chicks fed by both sexes, nestling period 12–15 days (but up to at least 17 days reported); fledglings fed by both parents. Nests parasitized by Brush Cuckoo (*Cacomantis variolosus*). At 23 nests with complete clutches in Townsville, eggs hatched in 13, and young fledged from seven (30.4%).

Movements. Apparently partly resident and partly migratory in Australia, although described also as nomadic in Australia and New Guinea, possibly in reference to essentially local movements; suggested that some nomadic movements in Australia misinterpreted as migration. Thought to be migratory in parts of NE Australia, moving or arriving in S in Aug and moving N in Apr–May, which partly supported by reporting rates in atlas surveys; suggested that some Australia breeders may winter in New Guinea, but no records of passage through Torres Strait.

Status and Conservation. Not globally threatened. Generally common in much of New Guinea, although oddly patchy distribution in NW & N parts, where recorded in W Vogelkop, with just isolated records along N coast, but these are apparently not referable to vagrants. Locally common in NE Australia; not recorded around Townsville (E Queensland) until late 1950s or early 1960s, but now well established.

69. Bar-breasted Honeyeater

Ramsayornis fasciatus

French: Méliphage fascié **German:** Wellenbrust-Honigfresser **Spanish:** Mielero Pechibarrado
Other common names: Fasciated/White-breasted Honeyeater

Taxonomy. *Glyciphila fasciata* Gould, 1843, Port Essington, Northern Territory, Australia.

Suggestions that populations from E Australia are intermediate between present species and *R. modestus* are not supported by any studies. No significant regional variation in plumage and size; proposed races *apsleyi* (from Melville I) and *broomei* (from Napier Broome Bay, in Kimberley Division) considered insufficiently differentiated. Monotypic.

Distribution. N Western Australia (Kimberley Division), Melville I and Top End of Northern Territory E to S Gulf of Carpentaria and N & E Queensland (Cape York Peninsula S to Atherton, and S on E coast to Rockhampton).

Descriptive notes. 13–14.5 cm; 12.5 g. Small rather plump honeyeater with short tail. Has top of head black, boldly scalloped white, narrow white supercilium (often finely mottled dark brown in front of and behind eye); side of head, chin and throat white, narrow blackish loreal stripe and black-brown malar stripe; upperparts grey-brown, darker on wing and tail, with diffuse blackish streaking on mantle, back and scapulars, narrow pale buff fringes on rectrices, fine white to buff fringes on median and greater secondary coverts, and fine buff fringes on tertials and edges of remiges (diffuse panel on folded wing); underbody

white, bold blackish broken barring on breast merging to black-brown spots on fore-flanks and dark brown streaks on rest of flanks; undertail dark grey, underwing creamy buff with dark grey trailing edge and tip; iris deep red-brown; bill dark brownish-grey, dirty pink on basal half, gape black or dirty pink; legs dirty pink or pink-brown. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but top of head light grey-brown with diffuse darker mottling, malar stripe duller and less obvious, breast streaked (not barred) dark brown, iris pale brown to grey, and gape yellow. **VOICE.** Rather quiet. Song a metallic, pleasant chatter. Main call a soft mewing “shrr, shrr” or “zzzzzz”, varying in frequency and intensity, given as contact; other calls include sharp, shrill rapidly repeated piping in alarm, soft purr, and sharp squawks.

Habitat. Seasonally inundated riparian paperbark (*Melaleuca*) forest and woodland bordering swamps or other wetlands; less often, open *Eucalyptus* forest and woodland, especially around or near wetlands. Sometimes in monsoon forest or vine thickets, such as semi-evergreen mesophyll vine forest; occasionally in gardens or on golfcourses; very occasionally in mangroves, thickets of *Acacia shirleyi*, or tropical heathland.

Food and Feeding. Mainly nectar and invertebrates (mostly insects, also spiders). Forages at all levels, among foliage of crowns, in vines and shrubs, occasionally on ground; often in paperbarks. Nectar obtained by probing flowers; invertebrates by gleaning and sallying, including sally-hovering, sally-striking in air and flutter-chasing; once seen to hover in front of spider web to pluck spider out. Takes nectar from wide range of flowering trees or shrubs (including *Melaleuca*, *Eucalyptus*, *Syzygium*, *Xanthostemon*, *Banksia*, *Grevillea*). Usually singly, in twos or in small flocks of up to ten individuals, once in flock of 30 or more; often with other meliphagid species when in flowering shrubs or trees. Defends feeding territories.

Breeding. Season broadly late spring to winter, with eggs recorded Nov–Jul and nestlings Feb–May, Jul and Sept; in Top End breeds almost exclusively in wet season, mainly Mar–Apr, when water levels in billabongs highest. Appears sometimes to nest in loose groups. Nest built by both sexes, bulky and domed, side entrance typically with landing, usually of strips of paperbark, bound with spider web, and lined with finer pieces of bark, but some made of dried grass, leaves or twigs and one lined with feathers, long pieces of bark may hang from sides and base, one nest 15.2 cm long, 10.2 cm wide, with entrance diameter 3.8 cm; suspended in foliage at end of slender branch of small tree or shrub (almost always paperbark), often low over water but can be well away from water, 0.3–7 m (mean 1.7 m) above ground. Clutch 1–3 eggs, usually 2 (mean 2.04); no information available on duration of incubation and nestling periods; it is probable that both sexes incubate; both feed nestlings and fledglings. Nests frequently parasitized by Brush Cuckoo (*Cacomantis variolosus*).

Movements. Probably largely resident. No seasonal movements observed. Vagrants recorded S of main range.

Status and Conservation. Not globally threatened. Locally fairly common. No estimates of global population; recorded densities of 0.5–0.16 birds/ha.

Genus *CONOPOPHILA* Reichenbach, 1852

70. Rufous-banded Honeyeater

Conopophila albogularis

French: Méléphage à gorge blanche **German:** Rostband-Honigfresser **Spanish:** Mielero Pechirrufo
Other common names: Rufous-breasted/Red-breasted/White-throated Honeyeater

Taxonomy. *Entomophila* ? *albogularis* Gould, 1843, Port Essington, Northern Territory, Australia. May form a superspecies with *C. rufogularis*. Populations of New Guinea and Torres Strait proposed as race *mimikae* (described from Mimika R, in SW New Guinea), but appear not to differ in plumage or size from Australian populations. Monotypic.

Distribution. Patchily in lowland New Guinea, at Sorong (W Vogelkop), along Sepik R, Markham R and upper Musa R (in N), and (in S) from Triton Bay E to Trans-Fly and Fly R, and at scattered sites in SE lowlands from Kerema E to Milne Bay; Aru Is; islands in Torres Strait; and N Australia from Melville I and Top End of Northern Territory (S to 15° S, E in coastal and subcoastal areas to Gove Peninsula), Groote Eylandt, and E to N Queensland (Cape York Peninsula).

ish-white with brownish-grey trailing edge and tip; iris brown to brownish-grey; bill black-brown, blue-grey base of lower mandible, blue-grey or pale grey gape; legs blue-grey to dark grey. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but with top and side of head browner (much as upperbody), no dark streaking on cap, merging into (not sharply demarcated from) off-white chin and throat, and with obvious narrow off-white eyering, underbody off-white, breastband reduced to faint pale brown wash at side (sometimes also on flanks), some also have pale buff centre of breast, bill grey-black with pinkish or orange base of lower mandible and gape. **Voice.** Song complicated and melodious; in New Guinea, one or two wheezy upslurs followed by clearer series of 5–8 notes in seesawing pattern, “szzweei, szzweei, whi-tsui-swei-tsui-swei-swtot-see-sot”, one 10-note song lasted 3–5 seconds. Most common call a repeated rising “zzheep”, or upslurred, wheezy “szzweei”, or clearer “sweei”. Other calls include, in New Guinea, a nasal chipping “nyah-zit” or “nyah-nyah” in flight, coarse squawking “kwee-kwee-kwee...” and nasal “zwee”; in Australia occasional cheeps, chattering and melodious twitter. In New Guinea, two birds often call together, one slightly after the other and both finishing abruptly.

Habitat. Open riparian paperbark (*Melaleuca*) woodlands surrounding wetlands; patches of monsoon vine forest (e.g. dry semi-deciduous monsoon vine thickets); and open and closed mangrove forests and woodlands on coasts (mainly where adjacent to other preferred habitats), but not normally within extensive mangrove forest. Sometimes in open forest or woodland of *Eucalyptus* or *Eucalyptus* and *Lophostemon* near wetlands with open grassy or shrubby sclerophyllous understorey; tends to avoid eucalypt forests and savanna in Australia, but more commonly in such habitats in New Guinea. Common in some cities, urban areas and towns and villages, in suburban parks and gardens and street trees, and in roadside vegetation. Unusually, one in scrub in swampy paddock on Sogeri Plateau, in SE New Guinea. Coastal lowlands and offshore islands; above 600 m on Sogeri Plateau.

Food and Feeding. Predominantly arthropods (mainly insects, also spiders), also nectar (e.g. of *Eucalyptus*, *Melaleuca*), occasionally arils attaching seeds to seedpods; seen also to take nectar from extra-floral nectaries on phyllodes of *Acacia umbellata*. Forages mostly in outer foliage of tree crowns, less often in lower canopy and shrub layer; fairly regularly on ground; seen to forage on aquatic vegetation in swamps (including reeds and water-lilies). Insects gleaned (e.g. from foliage, twigs and *Acacia* seedpods), caught also by sally-striking at foliage, sally-pouncing on to grass, sally-striking in air, probing and flutter-chasing; nectar taken by probing flowers. Arils sometimes plucked from seedpods of *Acacia auriculiformis*, rubbed against branch to remove seeds, then eaten. Usually forages singly or in twos (mostly pairs in territories), though occasionally in small flocks of 10–30 individuals; often in mixed-species feeding flocks, particularly with *C. rufogularis*.

Breeding. In New Guinea breeds through much of year, with peaks middle to late dry season and later in wet season; on Boigu I, in Torres Strait, eggs mid-Jan; in Australia breeding activity in all months, mainly Aug–May and concentrated Sept–Feb, in Darwin (Northern Territory) large peak in Sept–Oct (late dry season) and second, smaller peak in Jan–Mar (late wet season), pair may raise up to five broods. Both sexes collect material and build nest, a deep cup or purse made of fine strips of bark, grass, tips of palm fronds and other plant material, and spider web, lined with fine grass and bark fibre, external diameter 4–4 cm at rim and 5–7 cm at widest part, internal diameter 3–2 cm at rim, depth 5–7 cm; suspended by rim in thin horizontal fork of leafy branch, usually in centre or outer foliage of shrub or small tree, often over water, in New Guinea sometimes in clump of reeds; 195 nests Darwin 1–6–11 m (mean 5 m) above ground, elsewhere 0–5–10 m. Clutch 1–4 eggs, usually 2 (mean 2.16); incubation probably starts with or just before completion of clutch, by female only, period 14–17 days (once estimated fewer than 13 days in New Guinea); chicks brooded probably usually by female alone (but both members of pair seen to brood at one New Guinea nest), fed by both sexes, nestling period 13–15 days, in New Guinea suggested as 10–13 days; fledglings fed by both parents, remain with them for at least 30 days after fledging; adults sometimes start nest for subsequent attempt before young fledge. For 50 eggs in 23 nests, 0.95 young fledged per nest; twelve pairs in Darwin produced mean of 5.82 young per pair per season.

Movements. Resident, with some local erratic or nomadic movements, possibly by young birds. In ringing study in Darwin, adults appeared sedentary, but young possibly non-territorial floaters for months or years.

Status and Conservation. Not globally threatened. Common to very common in New Guinea; in Australia, recorded densities in Northern Territory of 12 birds/ha in Darwin and 0.3 birds/ha along S Alligator R. Colonized suburbs of Darwin in 1980s, well established by 1985, and presently ubiquitous and abundant. Distribution in New Guinea very patchy.

71. Rufous-throated Honeyeater

Conopophila rufogularis

French: Méléphage à gorge rousse **German:** Rostkehl-Honigfresser **Spanish:** Mielero Golirrufo
Other common names: Red-throated Honeyeater

Taxonomy. *Entomophila* ? *rufogularis* Gould, 1843, northern coast of Australia = Derby, King Sound, Western Australia.

May form a superspecies with *C. albogularis*. Slight clinal variation in tone of plumage, W and inland populations slightly paler and browner above and below. E populations (N Queensland) sometimes treated as a geographical race, *queenslandica* (described from Inkerman), but appear little different from birds in W of range. Monotypic.

Distribution. N Western Australia (Kimberley, including some offshore islands, e.g. Koolan and Cockatoo) E across Top End of Northern Territory (also Wessel Is, S to Tanami Desert and Barkly Tableland) and S of Gulf of Carpentaria (including Groote Eylandt and Wellesley Is) to N & E Queensland (S Cape York Peninsula, and E coast from about Gladstone S to Burnett R).

Descriptive notes. 11–14 cm; male 8.5–13.9 g, female 8.2–13 g. Small, plump honeyeater with short tail. Male is pale grey-brown above, slightly paler and greyer on top of head and neck, and off-white below; diffuse, fine dark streaking or mottling on top of head, off-white malar area, rufous-brown chin and centre of throat, and pale grey-brown wash on breast and along flanks; upperwing and uppertail slightly darker than upperbody, tertials with narrow pale fringes, greater secondary coverts with narrow dull-yellow fringes, rectrices and remiges with fine yellow edges (conspicuous yellow sides of tail, prominent yellow panel

on folded wing); undertail light grey; underwing brownish-grey, slightly paler on coverts and bases of remiges; iris olive-grey to dark brown; bill blackish, blue-grey base of lower mandible, sometimes off-white gape; legs dark grey or black. Female is like male but slightly smaller, with throat patch paler rufous-brown and less uniform (noticeable when partners compared directly). Juvenile is like adult but with conspicuous thin whitish eyering, no dark streaking on top of head, and off-white chin and throat lacking rufous patch, bill greyish with yellow or pinkish cutting edges and basal half of lower mandible, and gape initially swollen and yellow; immature as adult but most have chin and throat off-white or with scattered rufous-brown mottling, a few indistinguishable from adult female. **Voice.** Most vocalizations undescribed. Commonly utters chattering notes when foraging or nest-building; other calls include sharp, scratchy or peevish “zit-zit”, as contact or alarm, and rasping note. Single-phrase song otherwise undescribed; also light song (incompletely described), first notes given while in flight, the rest after alighting. Sometimes duets.

Habitat. Mainly open, grassy savanna woodlands, typically dominated by *Eucalyptus* and with scattered shrubs in understorey and ground cover of grasses such as spear-grass (*Stipa*), *Themeda*, *Sorghum* or spinifex (*Triodia*), e.g. open forest of Darwin woollybutt (*Eucalyptus miniata*) and Darwin stringybark (*Eucalyptus tetradonta*); or in riparian paperbark (*Melaleuca*) or *Eucalyptus*–*Melaleuca* woodlands, typically with shrubby understorey of *Acacia*, *Callistemon* and *Pandanus*, e.g. tall closed paperbark swamp-forest dominated by *Melaleuca leucadendra*, *Melaleuca cajuputi* and *Melaleuca symphyocarpa*. Sometimes in *Acacia* thickets, usually mixed with eucalypts and rainforest species, or in patches of rainforest or stunted monsoon forest; rarely, in mangroves. Sometimes in urban parks and gardens. Often in riparian vegetation in semi-arid environments.

Food and Feeding. Invertebrates (mostly insects, some spiders), also nectar (including from *Eucalyptus*, *Syzygium*, *Xanthostemon*, *Melaleuca*) and fruit (*Ficus*). Forages at all levels of vegetation; among foliage and flowers of trees and shrubs, also in air and, uniquely among honeyeaters, much on ground, including among long grass; at one site, often forages among emergent aquatic annuals. Insects mainly gleaned from foliage and branches, caught also by sally-striking in air or at foliage and branches (sometimes within a few centimetres of surface of water); also sally-hovers to take insects from foliage or close to ground, sally-pounces from low perch, flutter-chases and occasionally probes for prey. Obtains nectar by probing flowers. Active, acrobatic, conspicuous. Singly, in twos (often pairs) or in small flocks of up to 30 individuals; often in mixed-species flocks or in association with other honeyeaters in flowering trees or shrubs; mixed flock of 20 birds of present species and *Lichenostomus flavescens* once seen while feeding at swarm of termites (Isoptera).

Breeding. Season at least Jul–Mar; eggs recorded Jul, late Sept and Nov–Mar and fledglings early Jul. Nest probably built only by female (although also said that both sexes collect material and build), a neat, fragile pouch or purse made of grass, pieces of bark and twigs, loosely woven with spider web, lined with grass or rootlets, external diameter 5.8–7.8 cm, depth 5.2–7.6 cm, internal diameter 2.5–3.9 cm, depth 4.5–6.4 cm; suspended by one side from fork usually at leafy end of branch of shrub or tree, 1.2–10 m (mean 3.2 m) above ground. Clutch 2 or 3 eggs, mean 2.8; incubation probably by female alone, although some claims that both sexes incubate, period 13–15 days; chicks fed by female alone for first two days, thereafter by both sexes (female does most), nestling period 12 days; both parents feed fledglings. Nests parasitized by Brush Cuckoo (*Cacomantis variolosus*).

Movements. No clear patterns; variously considered sedentary, migratory and nomadic (even at same sites). Any movements undertaken probably related to availability of nectar, arrival and de-

parture in an area often coinciding with flowering of food trees or the end of flowering. Probably resident or partly resident throughout much of range, numbers fluctuating with movement of part of local population or possible influxes from elsewhere. Around Mt Isa (NW Queensland), where well studied, considered to be a breeding visitor, arriving Aug, with local dispersal to breed in Jan–Mar; mainly leaves Apr–May, but said also to move locally around Mt Isa when not breeding. These observations supported by bird-atlas reporting rates at Mt Isa (53.6% in summer and 20.3% in winter). At Mt Isa, said to arrive suddenly, moving rapidly in large flocks along watercourses, but to leave more gradually and in smaller numbers.

Status and Conservation. Not globally threatened. Locally common; less common in E, and rare in SE of range. Recorded densities of 0.08–0.40 birds/ha and, at various sites in N Northern Territory, mean of 0.35 birds/ha in wet season and 0.09 birds/ha in dry season. In Northern Territory, largely absent from N coast and much of E Arnhem Land.

Bibliography. 72. Grey Honeyeater
Conopophila whitei

French: Méléphage de White **German:** Grauhonigfresser **Spanish:** Mielero de White
Other common names: Alfred/Inconspicuous/White's Honeyeater

Taxonomy. *Lacustroica whitei* North, 1910, Lake Way, east Murchison Drainage, Western Australia.

Often placed in a monotypic genus, *Lacustroica*. Monotypic.

Distribution. Arid and semi-arid inland Australia: widely scattered records from W Western Australia E to C & S Northern Territory (S of 17° S) and, rarely, N South Australia.

Descriptive notes. 10–13 cm; male 7–10.3 g, female 9.4–11 g. Small, slim honeyeater with short tail. Plumage is nondescript brownish-grey above and white below, with partial thin pale grey eyering (broken in front of and behind eye), brownish-grey wash across breast and anterior flanks; uppertail dark grey-brown, finely edged white; upperwing blackish-brown, leading secondary coverts paler brownish-grey, greater secondary coverts and tertials with diffuse brownish-grey fringes, primaries with thin off-white edges and secondaries with thin olive-yellow edges (diffuse narrow olive strip on folded wing); undertail

dark grey with conspicuous broad white tips on outer few rectrices; underwing white, merging to dark grey trailing edge and tip, with some brown mottling along leading edge; iris dark brown to red-brown; bill grey, with pink-brown or blue-grey base of lower mandible (bill also described as wholly black), gape greyish or dull orange; legs dark grey or grey-black. Sexes alike in plumage; male slightly larger than female in tail length but not in other measures or in weight. Juvenile is like adult but browner above (slightly greyer top of head), with pale yellow wash on ear-coverts, malar area, chin and side of throat, merging to white on centre of throat, prominent narrow pale yellow to off-white partial eyering, breast washed creamy yellow and only faintly tinged brown, undertail-coverts washed pale yellow, most of remiges thinly edged pale olive-yellow (more extensive olive wash on wing), newly fledged young has pale orange, orange-yellow or yellow swollen gape. Voice. Most common call a loud and somewhat harsh, disyllabic “cre-seek”, second note higher than first, often rapidly repeated plaintive “troo-whyee, troo-whyee” or “tsee-you-whyee”; also a high silvery contact call. Song a rapid, high-pitched, sibilant and musical reel, in flight and when perched.

Habitat. Low acacia woodlands and shrublands, usually dominated by mulga (*Acacia aneura*), *Acacia tetragonophylla* and *Acacia citrinoviridis*, with scattered low shrubs and often lining stony or sandy creekbeds; possibly prefers mature stands. Also on sandhills with canegrass (*Zygochloa paradoxa*), scattered beefwood (*Grevillea striata*), red mulga (*Acacia cyperophylla*) and eucalypts. Sometimes in gardens of towns or homesteads, and recorded breeding in such.

Food and Feeding. Mostly insectivorous, seen to eat lerp and associated insects; also nectar and mistletoe (Loranthaceae) fruit. Forages mainly in foliage of trees and shrubs, often *Acacia*. Insects obtained mainly by gleaning from among foliage; seen also to sally-hover over crowns of plants to take insects from outer foliage. Obtains nectar from *Eremophila* by puncturing side of tubular flowers. Quiet and unobtrusive, but not shy. Singly, in twos (at least sometimes pairs) and in family groups; forages also in small flocks of up to eight individuals. Often with acanthizids, especially Yellow-rumped Thornbill (*Acanthiza chrysorrhoa*) and Western Gerygone (*Gerygone fusca*). Sometimes pauses for short periods with bill open and wings outstretched.

Breeding. Breeds in cooler months of inland, from late autumn to mid-spring, but few records; eggs mid-May, second half Aug and mid-Nov, nestlings late Oct and fledglings late Aug to late Oct. Nest built by both sexes, a thin cup made of grass, leaves, plant fibres and horsehair, bound together and attached to tree with spider web (one held together with sticky seed-coats), one nest loosely lined and covered on outside with woolly seeds, two others had many small white woolly lerp on outside, external diameter 5–7 cm; suspended c. 1 m to c. 2.5 m up at end of horizontal branch (sometimes forked) of narrow-leaved tree, often *Acacia*. Clutch 1 or 2 eggs; incubation said to be by both sexes; both feed nestlings and fledglings; no information on duration of incubation and nestling periods.

Movements. No information. Regularly reported at some sites, but sightings and occurrence unpredictable; described as resident or as nomadic and moving through much of C Australia, with no evidence for either.

Status and Conservation. Not globally threatened. Little known; uncommon to rare. Listed as “rare” in South Australia and “endangered” in Western Australia. At one site in Western Australia, five pairs recorded within radius of 1 km (c. 0.3 birds/ha). Most reliably reported at a few sites in inland Western Australia and at Kunoth Well (near Alice Springs), in Northern Territory. Breeding recorded at several widely scattered locations, but very few records. May be adversely affected by burning of vegetation and grazing by domestic and feral stock, which result in lack of regeneration of mulga habitats.

Genus *TIMELIOPSIS* Salvadori, 1876

73. Olive Straightbill
Timeliopsis fulvigula

French: Méléphage olivâtre **German:** Buschhonigfresser **Spanish:** Mielero Oliváceo
Other common names: Olive Straight-billed/Mountain Straight-billed Honeyeater, Mountain Straightbill

Taxonomy. *Euthyrhynchus fulvigula* Schlegel, 1871, Arfak Mountains, north-west New Guinea. Race *fuscicapilla* poorly differentiated, and possibly better merged with *meyeri*. Birds from Mt Goliath (in Orange Range) described as race *montana*, but very similar to SE New Guinea population of *meyeri* and synonymized with latter. Three subspecies recognized.

Subspecies and Distribution.

T. f. fulvigula (Schlegel, 1871) – mountains of Vogelkop and Onin Peninsula (Fakfak Mts), in NW New Guinea.

T. f. meyeri (Salvadori, 1896) – Central Ranges from Weyland Mts E, including Foja Mts and North Coastal Range (Bewani Mts), to SE New Guinea (including Mt Bosavi).

T. f. fuscicapilla Mayr, 1931 – mountains of Huon Peninsula, in NE New Guinea.

Descriptive notes. 13–15 cm; two males 20 g, two females 16–19 g (*meyeri*); two males 16–19 g (nominate); one male 22 g (*fuscicapilla*). Nominate race is largely dark olive to dark greyish-olive, slightly paler below, with varying brownish tinge on top of head and stronger greyish tone on lores, supercilium and ear-coverts (ill-defined greyish face), more brownish-olive remiges and rectrices, remiges with olive-yellow edges (conspicuous panel on folded wing), browner chin to breast; iris bright orange to red-brown; bill blackish-grey to black, sometimes paler grey base of lower mandible; legs grey-brown. Sexes alike in plumage.

age, male slightly larger than female. Juvenile is like adult but greyer below, iris dark grey to dark brown (specimens described with dark brown bill and yellow gape are probably juvenile or immature, but confirmation needed). Races differ only subtly in tone of plumage: *meyeri* is somewhat paler, less greenish, above than nominate, with buffish-grey chin and upper throat; *fuscicapilla* is very like previous, perhaps slightly darker. Voice. Call, frequently as contact during foraging, a plaintive or scolding, upwardly inflected series of “sreed-sreed-sreed...” or loud “screee screee”, latter given also in flight.

Habitat. Mid-montane forest and forest edge, mainly at c. 1100–2450 m, but to 2700 m in Snow Mts, and some specimens from 770 m inland of Hall Sound, in SE. In Eastern Highlands, recorded at 1760–2440 m, and to 2650 m in Mt Gahavisuka Provincial Park (near Goroka).

Food and Feeding. Insects recorded as eaten. Forages in understorey, including low dense vegetation at forest edge and dense thickets in damp areas within forest. Forages mainly by gleaning from foliage and probing curled leaves. Shy, skulking. Usually singly, in twos (possibly pairs) or often in small, noisy family parties of up to four individuals; occasionally in mixed flocks.

Breeding. Nest with egg in late Jan and female with egg in oviduct in late Jul, indicating breeding in wet and dry seasons. Nest an open cup, externally of dry blades of grass and internally of fine roots and other fibres, lined with feathers (including own). No other information.

Movements. No information; probably resident. Two ringed together in late Sept retrapped with a third individuals in early Dec.

Status and Conservation. Not globally threatened. Poorly known; generally considered scarce to rare. Locally fairly common at Biaru, near Wau; not abundant at Tari Gap.

Bibliography. Beechler (1978a), Beechler *et al.* (1986), Coates (1990), Coates & Peckover (2001), Coles (1995), Diamond (1972a), Frith & Frith (1992), Gibbs (1994), Gilliard & LeCroy (1961, 1970), Hartert (1930), Hicks & Burrows (1989), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Stein (1936).

74. Tawny Straightbill
Timeliopsis griseigula

French: Méléphage chamois **German:** Geradschnabel-Honigfresser **Spanish:** Mielero Habano
Other common names: Tawny Straight-billed/Grey-throated Straight-billed/Lowland Straight-billed/Babbler Honeyeater, Grey-throated/Lowland Straightbill

Taxonomy. *Euthyrhynchus griseigula* Schlegel, 1871, Sorong, Vogelkop Peninsula, New Guinea. Racial identity of apparently isolated populations of Gogol R, on NE coast (Madang Province), and R Waut (Morobe Province), on NW coast of SE peninsula, not certain; tentatively placed in, respectively, nominate and *fulviventr*. Two subspecies recognized.

Subspecies and Distribution.

T. g. griseigula (Schlegel, 1871) – NW & N New Guinea, from Vogelkop and Bomberai Peninsula (including Kumawa Mts) E to Humboldt Bay and extending to foothills of S Weyland Mts, also isolated population in R Gogol area (Madang Province).

T. g. fulviventr (E. P. Ramsay, 1882) – SE New Guinea on lower R Waut (Morobe Province) and E from R Kumusi and, on S coast, from E Gulf Province.

Descriptive notes. 18 cm; male 37–43 g and one female 34 g (nominate), 32 g (*fulviventr*). Nominate race is olive-brown above, with rufous tinge on uppertail-coverts, remiges and tail; off-white to buffy edges of remiges (paler panel on folded wing); underbody paler rufous, slightly darker posteriorly, underwing buff-brown with dark trailing edge and tip; iris red, red-orange, orange or red-brown; bill creamy to buff, with very base of culmen and lower mandible dark brown; legs pink. Sexes alike in plumage, male slightly larger than female. Juvenile is much as adult, but

Habitat. Lowland and foothill primary rainforest, also forest edge and tall secondary growth; sea-level to foothills, up to 800 m.

Food and Feeding. Arthropods (insects), fruit, nectar and flowers. Forages from understorey to upper canopy, often in lower and middle strata; of 41 observations of foraging in lowland rainforest at R Brown, most in understorey (38%, including 20% below 1 m), remainder in subcanopy 8–25 m above ground (22%), in upper canopy at 30–35 m (26%) and in lower canopy at 25–30 m (14%). Obtains food mainly by gleaning from foliage of trees, shrubs and vines, branches, palm fronds, debris and flowers; also probes dead curled leaves with bill. Active. When moving up vines, switches body from side to side with each upward movement; often hangs upside-down, flaring tail as it does, to probe or glean from leaves. Usually singly or in family parties of up to four individuals. Often in mixed flocks in which either Rusty Pitohui (*Pitohui ferrugineus*) alone or Rusty Pitohui and New Guinea Babbler are nuclear species, when foraging with latter behaves as integral part of flock; one seen in a mixed-species foraging flock repeatedly examining leaf petioles; at R Brown, foraged significantly closer to ground when in mixed-species flocks than when alone, and appeared to forage among debris and leaf litter disturbed by babblers.

Breeding. Poorly known. Appears to breed in dry season to early wet season (at least), and suggested as finishing late Jul to early Aug; juvenile male in early Aug, dependent fledglings and unspecified breeding noted early Nov, and breeding female mid-Dec. No other information.

Movements. Probably resident; resident in lowland forest near Brown R.

Status and Conservation. Not globally threatened. Patchily distributed throughout range. Generally uncommon; can be locally common, e.g. at Lohiki, in Gulf Province. Estimated density 0.1 bird/ha at Brown R. Presence of apparently isolated populations in NE may indicate that the species is more continuously distributed along N coast.

Bibliography. Anon. (1978c), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Bell (1982a, 1982b, 1982c, 1983a, 1984a, 1984b), Coates (1990), Coates & Peckover (2001), Diamond (1972a, 1985, 1987), Finch (1980b, 1983), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1964).

Genus *MELILESTES* Salvadori, 1876

75. Long-billed Honeyeater

Melilestes mearnsianus

French: Méliophage à long bec **German:** Langschnabel-Honigfresser **Spanish:** Mielero Piquilargo

Taxonomy. *Ptilotis mearnsianus* G. R. Gray, 1858, Aru Islands.

Race *stresemanni* possibly better merged with *vagans*, as birds on Batanta I appear intermediate between the two. Proposed race *brunneus* (from Siwi, in Arfak Mts) is synonymized with nominate. Three subspecies currently recognized.

Subspecies and Distribution.

M. m. vagans (Bernstein, 1864) – Waigeo and Batanta, in West Papuan Is.

M. m. mearnsianus (G. R. Gray, 1858) – West Papuan Is (Salawati and Misool), NW, S & E New Guinea (Vogelkop E to Weyland Mts and to Astrolabe Bay, Huon Peninsula and Milne Bay); Aru Is. *M. m. stresemanni* E. J. O. Hartert, 1930 – Yapen I and N New Guinea (Geelvink Bay E to Astrolabe Bay).

Descriptive notes. 20–23 cm; male 43–49.5 g and female 36.3–47.5 g (nominate), male 47–57 g and female 36–48 g (*stresemanni*). Drab honeyeater with very long and rather heavy bill strongly decurved over distal third. Nominate race has head and neck grey-brown, fine indistinct blackish streaking on top of head, faint and diffusely darker submoustachial stripe extending onto anterior ear-coverts (sometimes impression of pale orbital ring); chin and throat slightly paler, greyish-brown with yellow-olive tinge and diffuse paler mottling; upperparts dark brown to dark olive-brown, slightly browner (lacking olive) on wing-coverts,

remiges and uppertail; fine and faint buff-olive outer edges on remiges (most obvious on secondaries); breast, belly and anterior flanks as chin and throat, light greyish-brown with yellow-olive tinge (sometimes diffuse paler mottling on breast), merging to dull olive-brown rear flanks, vent and undertail-coverts; underwing brownish-grey, dirty orange-buff to buff lining and bases of remiges; undertail dark brownish-grey; iris bright orange to bright orange-red; bill black-brown to black, sometimes paler cutting edge on lower mandible; legs slaty blue-grey to black, soles yellow. Sexes alike in plumage, male larger than female; female possibly slightly paler than males, but confirmation needed. Juvenile is very different from adult, with much shorter, almost straight bill, which is also browner, conspicuous bright yellow eyering and yellowish gape, plumage dull olive-brown above, top and side of head diffusely barred or mottled darker, browner tail and wing with olive-brown outer edges of feathers (concealed rich buff inner edges of remiges), brown-streaked yellowish-buff below (streaking heaviest on breast and belly), rich buff underwing-coverts, legs horn to dark grey, iris probably dark (as immature). Race *stresemanni* has greyer, less olive, underbody and darker and browner upperparts than nominate; *vagans* differs from previous in cleaner grey and slightly more heavily streaked chin and throat, darker underbody, thicker bill (bill thicker also than that of nominate), possibly also has small area of bare skin around eye (confirmation

needed). Voice. Usual call a repeated whistled trisyllabic “whit whit whit” or “whit tt whit” (similar to a call of *Xanthotis flaviventris*); other calls include explosive “tick” in flight, and downslurred nasal mewing “chur-r-r” or metallic and plaintive “nyahn” or “nnr!”; single “ceez” as flight contact call, only infrequently heard.

Habitat. Dense vegetation in primary rainforest (but not monsoon forest), forest edge, tall riparian forest (around L Kutubu) and secondary growth, and other disturbed habitats, including 25-year-old and thinned plantation of *Araucaria cunninghamii*; occasionally in towns and gardens (including records of nesting). In Eastern Highlands, mainly in forest and secondary growth. Lowlands to lower mountains, from sea-level mainly to 1500 m, rarely to 2120 m; more common at lower altitudes. At Karimui, females predominate at lower altitudes, males at higher elevations.

Food and Feeding. Small arthropods (insects and spiders), small lizards (Scincidae), nectar, occasionally fruit (usually small, including raspberries); nestlings seen to be fed with small lizards. Forages at all heights, mainly in lower and middle storeys (to c. 10–15 m above ground), less often in canopy (to 35 m), in outer foliage at forest edge, or in secondary growth; males may spend less time in lower levels of vegetation. Of 65 observations in lowland rainforest at Brown R, 86% in understorey to 8 m above ground (49% 0–1 m above ground, 26% 1–2 m), rest in subcanopy at 8–25 m (8%), lower canopy at 25–30 m (5%) and upper canopy at 30–35 m (1%). Seen to forage on ground on flowers of the root parasite *Mitrasacme yamamotoi*. Gleans from foliage, bark, vines and rotten wood, and probes crevices in bark and curled leaves; often works its way up tree trunks in manner of Australasian treecreeper (Climacteridae), gleaning and probing close to trunk and branches, and seen to slide bill beneath bark when searching for food; sometimes hangs upside-down to forage on foliage. At Brown R (88 observations of 21 birds), all foraging by gleaning, 14% on trunks, 11% on branches, 19% on foliage, 5% on fruit, 32% on nectar, and 19% on rotten wood. As well as eating small fruits, probes and extracts pulp from holes made in larger fruits by parrots (Psittacidae); at Crater Mt seen to probe pulp of opened figs of *Ficus dammaropsis*. Infrequent visitor to canopy flowers, though forages at flowers on trunks more often. At Crater Mt, foraged at flowers of *Schefflera*, *Fagraea*, *Sloanea*, *Mucuna*, *Decasina hohlungii*, *Hibiscus*, *Musa* and *Syzygium*; elsewhere, seen to take nectar from large pink or red flowers at middle to canopy levels, from small canopy flowers of *Rhus taiensis*, and flowers of *Homesteadia* ginger close to ground. When feeding at flowers, base of bill and forehead can become dusted or caked with pollen. Shy, inconspicuous; rather slow-moving or leisurely when foraging. Usually seen singly, less often in twos (at least sometimes pairs); pairs thought to be territorial, with much fighting noticed. At Baiyer R, occasionally foraged with other honeyeaters.

Breeding. Season appears bimodal, from middle dry season to early wet season and, again, towards end of wet season (no breeding at height of wet season); at Baiyer River Sanctuary, one pair raised two broods between Oct and mid-Jan (first clutch laid 13th Oct, second 17th Dec), and had another clutch when observations recommenced in following early May; breeding recorded in S New Guinea in Jun–Dec and in Apr; adult feeding juvenile in mid-Sept at Crater Mt. Nest a fairly large, deep and thick-walled cup, exterior mainly of green moss and rootlets, at least sometimes with dead leaves and debris at base, interior of thin vines, vine tendrils and possibly rootlets, often lined with pinnales from large ferns, external diameter 19 cm, depth 11–14 cm; internal diameter 7–10 cm, depth 5.5–7 cm; one nest supported 1.2 m above ground between trunk and multiple leaf bases of a *Pandanus*, another 2 m up in dead foliage in sapling at forest edge, and at Baiyer River Sanctuary nest c. 2.5 m up in roofing material on underside of thatched roof in well-used building; site may be reused for subsequent nestings. Clutch 2 eggs; at two Baiyer R nests, incubation period 16 days and 18–19 days and nestling period 15 days and 14–15 days (nestling period at third nest 17 days). Longevity in ringing studies up to at least 7 years 3 months.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally common, although lack of conspicuousness gives impression of rarity; considered abundant at Crater Mountain Wildlife Management Area; common to uncommon at Baiyer R, and fairly common at Karimui. Estimated density in lowland rainforest at Brown R 1.8 birds/ha.

Bibliography. Bailey (1992), Beehler (1978a, 1980b, 1994), Beehler *et al.* (1986), Bell (1969, 1970c, 1982a, 1982b, 1982c, 1982e, 1984a, 1984b), Bishop (1977), Brown & Hopkins (1996), Clapp (1979a, 1980a), Coates (1990), Coates & Peckover (2001), Diamond (1972a), Finch (1980b, 1983), Fletcher (2000b), Gilliard & LeCroy (1961, 1966, 1967a, 1970), Greenway (1966), Gregory (1995b), Gyldenstolpe (1955a), Hartert (1930), Lamothe (1979), Mack & Wright (1996), Mackay (1981), Murray (1988b), Rand (1942a), Rand & Gilliard (1967), Richards & Suryadi (2002), Ripley (1964), Schodde & Hitchcock (1968), Symes & Marsden (2005), Wahlberg (1993).

Genus *STRESEMANNIA* Meise, 1950

76. Bougainville Honeyeater

Stresemannia bougainvillei

French: Méliophage de Bougainville

Spanish: Mielero de Bougainville

German: Bougainvillehonigfresser

Taxonomy. *Lichmera bougainvillei* Mayr, 1932, Bougainville Island.

Relationships uncertain. Has in the past been placed variously in *Lichmera*, *Meliphaga*, *Melilestes* and the now defunct genus *Vosea*. Retained in current monotypic genus pending resolution of its relationships. Monotypic.

Distribution. Bougainville I, in N Solomons.

Descriptive notes. 17–18 cm. Male has head, neck and upperbody drab olive-grey, merging to slightly paler grey on chin and throat, and with fine and diffuse dark olive-brown mottling on forehead and crown; upperwing and uppertail dark olive-brown to dark olive-grey, faintly paler olive outer edges of rectrices and remiges (greenish wash or panel on folded wing); underbody pale olive-grey, with buff tinge on flanks, vent and undertail-coverts; underwing buffy grey, dark grey-brown trailing edge and tip; iris brown to reddish-brown; bill black to dark slate-grey; legs bluish-grey to leaden grey. Female is slightly smaller than

male; suggested that plumage perhaps greyer and less strongly toned olive ventrally, and top of head tending to appear more mottled, but confirmation needed. Juvenile is greyer than adult, lack-

ing brown tones, and with diffuse greyish mottling on underbody, bill paler, dark grey, and gape prominent and yellow. **VOICE.** Vocalizations include short series of 4–5 mellow whistled notes, the first rising and falling and subsequent notes alternately rising and falling (likened to calls of *Ptiloprora guisei*); dry and raspy “chht chht”. **Habitat.** Primary montane forest, including cloudforest; described as numerous in mixed bamboo and tree-fern. From c. 700 m to above 1950 m. **Food and Feeding.** Insects and fruit; probably also nectar, but not seen to congregate in flowering trees. Forages in canopy, by gleaning from inner canopy of trees; also close to ground in forest. Quiet, shy, but reasonably active. Usually in twos (probably pairs). Two individuals once seen to fly up at each other, before returning to same perches and then disappearing into vegetation, possibly a territorial interaction. **Breeding.** One nest described: a substantial cup, interior of neatly woven rootlets and other vegetable fibres, exterior covered with green moss and small ferns (appearing fresh and green), external depth c. 13 cm, internal diameter 6 cm and depth 8–9.5 cm, built in small leafy tree 3 m tall; contained 1 egg. No further relevant information, although egg described. **Movements.** Resident. **Status and Conservation.** Not globally threatened. Restricted-range species: present in Solomon Group EBA. Poorly known. Described as reasonably common or generally scarce. **Bibliography.** Coates (1990), Diamond (1975a), Doughty *et al.* (1999), Finch (1985), Hadden (1981, 2004), Mayr (1932, 1945b, 1955, 1971), Mayr & Diamond (2001), Stattersfield *et al.* (1998).

Genus *GLYCIFOHIA* Mathews, 1929

77. Barred Honeyeater

Glycifohia undulata

French: Méliphage barré **German:** Sperberhonigfresser **Spanish:** Mielero Barrado
Other common names: New Caledonian Honeyeater

Taxonomy. *Certhia undulata* Sparrman, 1787, no locality = New Caledonia. Genus sometimes subsumed in *Phylidonyris* or in *Guadalcanaria*. Monotypic. **Distribution.** New Caledonia.

Descriptive notes. 16–20 cm; one female 16 g. Distinctively marked honeyeater with long, slender and fairly strongly decurved bill. Top of head, hindneck and side of neck are dark olive-brown, fine whitish scalloping at side of crown grading to bolder white scalloping on neck; lores, patch around eye and narrow stripe above and behind eye dusky black, contrasting with finely black-speckled silvery grey-white ear-coverts; broad off-white malar stripe extends to side of neck, becoming finely scalloped black rather variably, sometimes only posteriorly, and meeting (or almost meeting) largely clear whitish band (diffusely scaled slightly darker) curving across lower throat; isolated brownish-black chin and upper throat, broken up towards lower throat by sparse whitish barring; upperparts brownish-grey to dark brown, diffusely streaked and scaled paler olive-grey or brown on mantle, back and scapulars, upperwing-coverts with fine pale margins (reduced or lost with wear), remiges with yellow-olive edges (conspicuous on folded wing), uppertail dark brown; underbody off-white to very pale grey with broken blackish-brown barring, this bold on anterior flanks and breast (where merging with barring of side of neck), paler and less heavy on lower underbody, and faint or sometimes absent in centre of belly and vent; undertail pale brownish-grey, underwing pale buff-white with silvery brownish-grey trailing edge and tip; with wear plumage becomes browner and pattern duller; iris dark brown to red-brown; bill black; legs blue-grey to dark grey. Sexes alike in plumage, male larger than female. Juvenile is duller and slightly paler than adult, with only faint barring below. **VOICE.** Flute-like whistle, “phew”, sometimes of 2–3 or more syllables, often preceded by long descending trill.

Habitat. Primary rainforest, tall secondary growth and maquis (scrubland) vegetation; also in gardens and niaouli (*Melaleuca leucadendra*) savanna woodland when foodplants flowering. More common in hill and montane vegetation.

Food and Feeding. Nectar (including of *Geissois* and *Grevillea*), small insects, some fruit. Acrobatic, hanging and clambering about flowers and branches. Seen singly or in small parties, congregating in flowering trees. Pugnacious, fighting with conspecifics or other species.

Breeding. Breeds Aug–Jan. Nest cup-shaped, made of dead grasses and ferns, with soft woolly lining (probably of sedge inflorescences), or lined with feathers, some covered externally with fern or moss, external diameter 9 cm, depth 6 cm, internal diameter 6.5 cm, depth 3.5 cm; well concealed 0.3–1.6 m (mean 1.2 m) above ground, one within small *Xanthostemon auranticum* shrub, attached to grasses and a branch of the shrub. Clutch 1 egg; both parents incubate eggs and rear young; no information on duration of incubation and nesting periods.

Movements. Nothing known; probably sedentary, with some local movements. **Status and Conservation.** Not globally threatened. Restricted-range species: present in New Caledonia EBA. Described as not uncommon or as common in all humid habitats in New Caledonia. First nest not described until 1976. **Bibliography.** Anon. (2007q), Doughty *et al.* (1999), Hannecart & Létocart (1980), Layard & Layard (1882), Mayr (1945b), Ross (1988), Stattersfield *et al.* (1998), Stokes (1978, 1980).

78. Vanuatu Honeyeater

Glycifohia notabilis

French: Méliphage des Nouvelles-Hébrides **Spanish:** Mielero Ventriblanco
German: Weißbauch-Honigfresser
Other common names: Vanuatu Mountain/New Hebrides/White-bellied/White-breasted Honeyeater

Taxonomy. *Glyciphila notabilis* Sharpe, 1899, Vanua Lava, Banks Islands, Vanuatu. Genus sometimes subsumed in *Phylidonyris* or in *Guadalcanaria*. Races weakly differentiated. Two subspecies recognized.

Subspecies and Distribution. *G. n. notabilis* (Sharpe, 1899) – Banks Is (Uréparapara and Vanua Lava), Espiritu Santo and Ambae, in N & C Vanuatu. *G. n. supercilialis* (Mayr, 1932) – C Vanuatu (Maewo, Pentecost, Malakula, Ambrym, Paama and Epi).

Descriptive notes. 18–21.5 cm; one male 29.7 g, two females 23.3 g, 26.4 g. Nominate race has top and side of head black, fine white speckling on forehead and varying onto crown, grading to bolder white barring towards side of crown and merging into prominent black-speckled white supercilium that extends well behind eye to upper side of neck; also flecked and speckled with white on malar area, ear-coverts and brownish side of neck, leaving weakly defined blackish eyestripe (pale flecking on rear ear-coverts sometimes forms silvery patch); hindneck and upperbody rich brown to rufous-brown, tail brown to olive-brown; upperwing brown to olive-brown, coverts with fine rufous-brown fringes, remiges with fine rich brown to rufous-brown outer edges (folded wing appears largely rich rufous-brown); chin, throat and underbody off-white, with sparse, fine and long brownish or dusky streaking on breast, belly and flanks, pale brownish mottling or wash on vent and undertail-coverts; undertail grey-brown, underwing pale rufous-brown with greyish-brown trailing edge and tip; iris dark brown; bill black; legs blue-grey. Sexes alike in plumage, female smaller than male. Juvenile is duller than adult, supercilium creamy white, upperbody darker with fine pale streaking, margins of wing-coverts broader and paler, buff-cinnamon or olive-cinnamon, pale yellow wash on belly, sometimes also on chin, throat and ear-coverts, lacks distinct dark streaking below but some diffuse dusky streaks on lower throat and upper breast. Race *superciliaris* differs from nominate most obviously in more marked white supercilium, much whiter and more prominent malar stripe and lower ear-coverts (less broken up by blackish speckling), better-defined black eyestripe, less speckling and barring on crown, also slightly browner upperbody (subtle). **VOICE.** Highly vocal, with range of ringing calls. Main call one of the most characteristic sounds of highlands and one of first calls of dawn chorus: a loud, powerful, ringing flute-like “tyau” or “tyjau”. Other calls include loud, prolonged “toowyt”; harsh “tchea” in alarm; moderately loud somewhat plaintive “teewee”. Song, occasionally from exposed perch, a rich and varied series of pleasant flute-like notes and whistles, e.g. “teewee-twytwytee” or “teewee-teeeeee”. Possibly mimics other birds.

Habitat. Hill and montane primary forest and tall secondary growth, occasionally lowland forests and mangroves; usually in extensive tracts of forest. Sea-level to at least 1250 m, primarily in highlands above 450–850 m. **Food and Feeding.** Nectar, pollen, insects, spiders, probably fruit. Forages from canopy down to understorey; searches among foliage and flowers, gleaning and probing for arthropods and nectar; also makes short sallies for flying insects. Rapidly probes flower before moving to next, then flying to another plant. Conspicuous, highly active and noisy; seen singly, in twos (probably pairs) and in small parties of up to 15 individuals. **Breeding.** Very poorly known. Said to breed Sept–Jan, with unspecified evidence of breeding Oct–Nov. Nest cup-shaped; clutch 2 pale eggs. No other information. **Movements.** Resident, probably with some local movements. Described as moving from high altitude to sea-level on Espiritu Santo, but no further details. **Status and Conservation.** Not globally threatened. Restricted-range species: present in Vanuatu and Temotu EBA. Widespread and common. **Bibliography.** Bregulla (1992), Diamond & Marshall (1976, 1977b), Doughty *et al.* (1999), Kratter *et al.* (2006), Marshall & Harrison (1941), Mayr (1932), Medway & Marshall (1975), Stattersfield *et al.* (1998).

Genus *MYZA* A. B. Meyer & Wiglesworth, 1895

79. Lesser Streaked Honeyeater

Myza celebensis

French: Méliphage des Célèbes **German:** Celebeshonigfresser **Spanish:** Mielero Chico de Célebes
Other common names: Celebes/Dark-eared/Lesser Sulawesi Myza, Brown(!)/Celebes/Dark-eared/Lesser Sulawesi Honeyeater, Brown Honeysucker

Taxonomy. *Arachnothera* ? *celebensis* A. B. Meyer and Wiglesworth, 1894, Bone Mountains, Gorontalo, north Sulawesi. Relationships of genus uncertain, suggested as possibly closest to *Ptiloprora* and *Melidectes*; ear-lier, was placed close to *Lichmera*. Proposed race *parvirostris* (from Mt Tanke, in Mengkoka Mts, SE Sulawesi) subsumed within nominate. Two subspecies recognized.

Subspecies and Distribution. *M. c. celebensis* (A. B. Meyer & Wiglesworth, 1894) – N, C & SE Sulawesi. *M. c. meridionalis* (A. B. Meyer & Wiglesworth, 1896) – S Sulawesi.

Descriptive notes. 17 cm; three males 19.5–22.5 g. Nominate race has top of head and neck grey to tawny-olive, finely streaked dark olive-brown, merging to largely dark olive-brown supercilium; dark olive-brown line beneath eye curving up behind eye to meet rear supercilium, and enclosing bold whitish orbital ring, which is narrow or broken at front; lores pale grey, finely speckled darker (brown); malar area, ear-coverts and side of neck dark olive-brown, finely speckled or mottled light grey-brown, merging to yellowish-grey on chin and throat, which evenly streaked or mottled dark olive-brown; upperbody brownish-grey, streaked and mottled dark olive-brown to blackish; upperwing dark olive-brown, pale olive to yellow-olive outer edges of remiges (diffusely olive panel on outer edge of folded wing); breast yellowish-grey, evenly streaked or mottled dark olive-brown, merging to dark olive-brown on rest of underparts, scaled and streaked paler yellowish-grey except on centre of belly; undertail dark

brown to dark olive-brown, underwing dark olive-brown with pale buff lining; iris dark brown; bill glossy black, sometimes tiny pale brown tip; legs dark brown to grey-brown or green-grey, soles yellow to yellow-orange. Sexes alike in plumage, male much larger than female. Juvenile undescribed. Race *meridionalis* is slightly smaller than nominate, also slightly darker and greyer above, and darker with finer and weaker streaking below. **VOICE.** Main call a sharp, harsh "treet" or harsh "kik". Song a slurred series of twittering squeaks or harsh twittering.

Habitat. Occupies montane rainforest, mainly in primary forest, including moss forest. More often on lower slopes than on ridges; from c. 900 m up to 2500 m. Replaced at higher altitudes by *M. sarasinorum*.

Food and Feeding. No details of diet. Forages mainly in lower stages, less often in canopy, but feeds in crowns of flowering trees, including in flowering mistletoes (of genus *Loranthus*); forages at flowers, and by gleaning from branches, vines and other hard surfaces. Singly or in twos (probably pairs); sometimes in or at edges of mixed-species flocks of insectivores.

Breeding. No information.

Movements. No information; probably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in Sulawesi EBA. Widespread and common. Continuing threats to habitat, through logging and clearing, potentially of concern.

Bibliography. Coates & Bishop (1997), Riley, J. (2000), Riley, J. & Mole (2001), Riley, J.I. (1924), Rozendaal & Dekker (1989), Salomonsen (1966a), Stattersfield *et al.* (1998), Stresemann & Heinrich (1940b), Watling (1983), White & Bruce (1986).

80. Greater Streaked Honeyeater

Myza sarasinorum

French: Méléphage à points **German:** Sarasinhonigfresser **Spanish:** Mielero Grande de Célebes
Other common names: Greater Sulawesi/White-eared/Meyer's/Mengkoka/Spot-headed Honeyeater, White-eared/Sarasin's Myza, Spot-headed Honeysucker

Taxonomy. *Myza sarasinorum* A. B. Meyer & Wiglesworth, 1895, Matinan Mountains, north Sulawesi.

Relationships of genus uncertain, suggested as possibly closest to *Ptiloprora* and *Melidectes*; earlier, was placed close to *Lichmera*. Three subspecies recognized.

Subspecies and Distribution.

M. s. sarasinorum A. B. Meyer & Wiglesworth, 1895 – N Sulawesi.

M. s. chionogenys Stresemann, 1931 – NC & SC Sulawesi.

M. s. pholidota Stresemann, 1932 – SE Sulawesi.

Descriptive notes. 20 cm. Nominative race has top and side of head and neck blackish with fine slate-grey streaking, fine blackish supercilium and lores, and large bare violet ear-patch extending from beneath eye and expanding behind eye onto upper side of neck; chin and throat blackish, diffusely streaked or mottled greyish; upperbody dark brownish-black, heavily streaked grey, upperside brownish-black with reddish-brown feather edges; underbody dark reddish-brown, fine blackish streaking on breast and belly; iris brown; bill and legs black. Sexes alike in plumage, male much larger than female. Juvenile undescribed.

Race *chionogenys* differs from nominate in having whitish ear-patch, olive-green streaking on upperbody and bolder black streaking below; *pholidota* is more like nominate, but differs in more brownish-grey underbody with bolder blackish streaking. **VOICE.** Main call a characteristic sound of high montane rainforest, a chiming monosyllabic "zunk" or, less often, a double "zunk-zunk", with second note lower-pitched. Song a series of high-pitched squeaks (like those of *M. celebensis*); also series of short, sharp "kep" notes, repeated for long periods at rate of 2–4 per second (hoarse "kik...kik" probably the same); call of 3–5 high-pitched wheezy notes and lasting less than 1 second, given at long and irregular intervals during foraging; and occasionally a sharp "zip".

Habitat. Upper montane rainforest and elfin moss forest, on ridgetops, from 1700 m to 2800 m, mainly above 2000 m. Replaced at lower altitudes by *M. celebensis*.

Food and Feeding. Diet includes nectar; doubtless also insects. Usually forages above middle storey, in upper stages and canopy, occasionally descends to lower levels to exploit flowering shrubs: seen to forage in mistletoes (of genus *Loranthus*) in canopy. Active and aggressive, with somewhat jerky movements; rapidly hops or flies from one inflorescence to another and disappears into foliage. In Lore Lindu National Park, occasionally recorded in mixed-species foraging flocks.

Breeding. Female with egg in oviduct in early Jul. No other information.

Movements. No information; probably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in Sulawesi EBA. Common or abundant, and widespread on much of Sulawesi (not in S). Threats to forest habitats potentially of concern.

Bibliography. van den Berg & Bosman (1986), Coates & Bishop (1997), Ekstrom *et al.* (1998), Stattersfield *et al.* (1998), Stresemann & Heinrich (1940b), Watling (1983), White & Bruce (1986).

Genus MELIPOTES P. L. Sclater, 1874

81. Spangled Honeyeater

Melipotes ater

French: Méléphage pailleté **German:** Huonhonigfresser **Spanish:** Mielero Moteado
Other common names: Black/Huon Honeyeater, Huon Melipotes

Taxonomy. *Melipotes ater* Rothschild & E. J. O. Hartert, 1911, Rawlinson Mountains, Huon Peninsula, north-east New Guinea.

Genus closely related to *Macgregoria*. Forms a superspecies with *M. gymnops*, *M. fumigatus* and *M. carolae*. Monotypic.

Distribution. Mountains of Huon Peninsula, in NE New Guinea.

chevron-shaped or crescent-shaped to small and triangular or rounded (variation possibly associated with wear); iris dark brown to red-brown; bill black or grey-black; legs blue-grey. Sexes alike in plumage, male probably larger than female. Juvenile undescribed. **VOICE.** Typically quiet, but noisier than congeners. Calls include repeated deep "chut chut".

Habitat. Occupies montane forests and also tall secondary growth; recorded from c. 1200 m up to 3300 m.

Food and Feeding. Poorly known. Predominantly frugivorous. Mainly in canopy or subcanopy, foraging for fruit. Conspicuous. Usually singly or in twos (probably pairs); more sociable or less aggressive than congeners.

Breeding. No information.

Movements. No information; almost certainly sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in Adelbert and Huon Ranges EBA. Poorly known; considered generally common. Described as common above Satop in Nov 1992.

Bibliography. Beehler (1978a), Beehler, Pratt & Zimmerman (1986), Beehler, Prawiradilaga *et al.* (2007), Coates (1990), Coates & Peckover (2001), Eastwood & Gregory (1995), Richards & Rowland (1995).

82. Arfak Honeyeater

Melipotes gymnops

French: Méléphage à ventre tacheté

German: Fleckenbauch-Honigfresser

Spanish: Mielero de las Arfak

Other common names: Arfak/Western Melipotes, Bare-eyed/Western Smoky/Large/Spot-bellied Honeyeater

Taxonomy. *Melipotes gymnops* P. L. Sclater, 1874, Hatam, Arfak Mountains, Vogelkop, north-west New Guinea.

Genus closely related to *Macgregoria*. Forms a superspecies with *M. ater*, *M. fumigatus* and *M. carolae*. Status and affinities of populations of this genus in Fakfak Mts (Onin Peninsula) not known: three sightings in 1981 of honeyeaters that looked more like *M. fumigatus* (closest known populations in Kumawa Mts, to SE) than like present species (range to N), and one seen in 1992 had ventral plumage more like that of present species but facial patch somewhat like that of *M. ater* (thus unlike those seen in 1981); further research required. Monotypic.

Distribution. Tamrau Mts, Arfak Mts and Wandammen Mts, in NW New Guinea.

Descriptive notes. 21.5–22 cm; male 58–61.5 g, female 48–58 g. Head, neck, breast, upper belly and flanks are sooty black to grey-black, with large circumorbital patch of bright yellow skin (facial patch flushes bright red when bird agitated, and may be partly red and yellow at times), and distinctive short cream to buff-white streaks on side of upper breast, lower breast, belly and flanks, merging into pale ochre on centre of lower belly, vent and undertail-coverts; blackish colour of head and neck merges into dark grey-brown to brownish-grey on upperparts; tertiaries and upperside-coverts probably have paler tips or fringes, at least when fresh; uppertail grey-black with fine paler outer edges, undertail light brownish-grey; iris dark brown to red-brown; bill black, grey-black or blackish-brown; legs grey-black to brownish-tinged or dark blue-grey. Sexes alike in plumage, male on average slightly larger than female. Juvenile undescribed. **VOICE.** Call "wee wee wee...", while perched or in flight.

Habitat. Montane forest, forest edge and native agricultural gardens; 1200–2700 m, but said also to reach 3680 m.

Food and Feeding. Predominantly frugivorous, but insects also taken; seeds found in one stomach. Forages at all levels, mostly in canopy; also in shrubs and trees in agricultural gardens. Active, noisy and conspicuous. Usually solitary; also in small flocks at food sources.

Breeding. No information.

Movements. No information; almost certainly sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in West Papuan Highlands EBA. Poorly known; considered generally common or abundant.

Bibliography. Beehler, Pratt & Zimmerman (1986), Beehler, Prawiradilaga *et al.* (2007), Coates (1990), Coates & Peckover (2001), Diamond (1985), Gibbs (1994), Gyldenstolpe (1955b), Hartert (1930), Hoogerwerf (1971), Hornbuckle (2001), Rand (1936b).

83. Common Smoky Honeyeater

Melipotes fumigatus

French: Méléphage enfumé **German:** Aschbrust-Honigfresser **Spanish:** Mielero Ahumado

Other common names: Common/Smoky Honeyeater, Smoky Bare-eyed/Yellow-faced Honeyeater, Eastern Smoky Honeyeater, Common/Eastern Melipote(s)

Taxonomy. *Melipotes fumigatus* A. B. Meyer, 1886, Hufeisengebirge (south-east Owen Stanley Range), south-east New Guinea.

Genus closely related to *Macgregoria*. Forms a superspecies with *M. ater*, *M. gymnops* and *M. carolae*. Status and affinities of populations of this genus in Fakfak Mts (Onin Peninsula) not known: three sightings in 1981 of honeyeaters that looked more like present species (closest known

populations in Kumawa Mts, to SE) than like *M. gymnops* (range to N), and one seen in 1992 had ventral plumage more like that of *M. gymnops* but facial patch somewhat like that of *M. ater* (thus unlike those seen in 1981); further research required. Also, earlier published statements that present species abundant in Foja Mts above 1200 m presumably refer to newly described *M. carolae*. Race *goliathi* intergrades with nominate in Herzog Mts. Three subspecies recognized.

Subspecies and Distribution.

M. f. kumawa Diamond, 1985 – Kumawa Mts, in NW New Guinea (S Bomberai Peninsula).
M. f. goliathi Rothschild & E. J. O. Hartert, 1911 – Central Ranges from Weyland Mts and Nassau Mts E to Bismarck–Kubor Mts (including Mt Bosavi) and W Herzog Mts, also Cyclops Mts and C North Coastal Range (Bewani Mts).
M. f. fumigatus A. B. Meyer, 1886 – E Herzog Mts and mountains of SE New Guinea.

wing-coverts and olive-brown to grey-olive edges of feathers of alula and remiges; underbody dark grey-brown to dark olive-brown (contrasting with paler throat), with very faint and fine rufous-brown shaft streaks across upper breast, diffuse pale grey to light grey-brown feather edges forming pale mottling, and light grey-brown thighs; undertail dark grey-brown; underwing pink-buff to buff on coverts, with pale grey-brown bases of remiges and olive-brown trailing edge and tip; iris dark brown to red-brown; bill black, rarely cream tip of upper mandible; legs slate-grey to dark blue-grey or brownish-grey. Sexes alike in plumage, male slightly larger than female. Juvenile is said to be like adult but browner (not so black) above, duller and more uniformly grey below, palest on chin and throat but largely lacking paler mottling, and legs greenish-brown to dusky olive-green. Race *goliathi* differs from nominate in darker, more blue-grey, underparts and more blackish upperparts, also much larger size (increasing clinally with altitude); *kumawa* differs from others in blackish chin and throat contrasting little with rest of head, bold black-and-white crescent-shaped scaling (not diffuse mottling) on lower breast and belly, clear white (not diffusely grey) tips on upperwing-coverts, larger and whiter pale area on underwing, also appears larger than nominate and similar in size to previous (but few data). VOICE. Generally silent; occasionally a thin “sit sit sit” or weak sibilant “swit swit swit...” repeated monotonously; said also to give a series of 6 rather slow and soft, high-pitched notes, upslurred at end; “see” sometimes given in flight; and chipping notes. One adult, near nest with young, gave plaintive squeaking “wheet-wheet-wheet...” unceasingly, possibly as distraction or alarm in response to presence of observer.

Habitat. Mid-montane and montane primary forest, including high-altitude stunted moss forest, forest edge, secondary growth (particularly dense secondary growth in natural clearings), and disturbed and modified habitats, including gardens. From 750 m (Ok Tedi area) to 4200 m (Snow Mts), but rarely below 1100 m and mainly 1400–3400 m (timber-line over most of species’ range); to c. 2800 m in SE. Across altitudinal gradient on Mt Karimui, only immatures at 1100–1370 m and mainly females at 2160–2490 m, with breeding males not found below 1830 m.

Food and Feeding. Predominantly frugivorous, but insects and some floral parts also taken; not known to eat nectar, and one observed while pecking at flowers was found to have only insects (attracted to flowers) in stomach. Takes mainly small fruits 2–8 mm in diameter (including of *Sericolea pullei*), which swallowed whole; also eats pulp of larger fruits by pecking. Mainly in canopy to middle stages and shrubs at edge of forest, but occurs at all levels. Various rather slow-moving and highly active. Forages mainly by gleaning, occasionally hanging with head downwards; occasionally sally-strikes at insects. Conspicuous, often perches in open. Usually seen singly, less often in twos (probably pairs), rarely in small parties of 5–6 individuals; at least once seen in mixed-species flock, and said often to be seen with *Melidectes belfordi*. Often aggressive, sometimes chases conspecifics, and drives other species, including Superb Bird-of-paradise (*Lophorina superba*), from feeding sites; conversely, seen to be chased from a tree by Ribbon-tailed Astropia (*Astrapia mayeri*).

Breeding. Season at least late dry season, with eggs late Sept and early Oct, and nestlings and fledglings late Aug to late Oct, and unseen nestling heard in Dec; birds in breeding condition Aug–Nov. Nest a large and rather bulky, loose pensile cup of long, thin mosses, a few leaves and other plant material, sparingly bound together and to nesting plant with long fungal fibres, one with large pieces of rotten *Pandanus* leaves attached to exterior and few green fern fronds on inside, lined with coarse dead leaves and ferns or rootlets, one nest had external diameter 14 cm, depth 14 cm, internal diameter 7 cm, depth 6 cm; usually suspended by rim from horizontal fork 4.5–12 m above ground near end of branch of small tree. No information on clutch size and on incubation and nestling periods; at one nest, young fed with fruit by one adult while other called in distraction or alarm (apparently at presence of observer).

Movements. Almost certainly largely sedentary or resident, possibly with some local movements, e.g. a few at 1200 m at Crater Mt thought to be transients from higher altitudes, and sporadic records down to 750 m in Ok Tedi area possibly related to shortages of food at higher altitudes.

Status and Conservation. Not globally threatened. Considered generally common to abundant, and ubiquitous in Central Ranges.

Bibliography. Beehler (1978a), Beehler, Pratt & Zimmerman (1986), Beehler, Prawiradilaga *et al.* (2007), Bell (1969), Coates (1990), Coates & Peckover (2001), Diamond (1972a, 1985), Filewood (1969), Frith & Frith (1992), Gilliard & LeCroy (1961, 1968), Gregory (1995b), Gyldenstolpe (1955a), Hartert (1930), Heron (1977a), Hopkins (1992), Mack & Wright (1996), Mayr & Gilliard (1954), Mayr & Rand (1937), Melville (1979), Murray (1988b), Rand (1942b), Ripley (1964), Schönwetter & Meise (1981), Sims (1956), Tolhurst (1991), Watson *et al.* (1962), Weston (1977).

84. Wattled Smoky Honeyeater

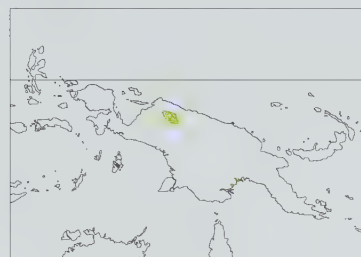

Melipotes carolae

French: Méléphage de Carol **German:** Carolahonigfresser **Spanish:** Mielero de Carlota
Other common names: Farfak Honeyeater

Taxonomy. *Melipotes carolae* Beehler *et al.*, 2007, Bog Camp (2°34′S, 138°34′E), 1650 m, Sarmi District, Papua Province, north-west New Guinea.

Genus closely related to *Macgregoria*; the fleshy wattle of this species provides a morphological link between the two. Forms a superspecies with *M. ater*, *M. gymnops* and *M. fumigatus*. Monotypic.

Distribution. Foja Mts, in NW New Guinea.

upperparts, largely black-brown, with (when fresh) very fine paler greyish outer edges and tips on median and greater coverts and tertials and pale greyish or olive-greyish outer edges on rest of remiges (outer edges of remiges fade with wear); uppertail grey-black with fine paler outer edges; chin and upper throat dark grey, slightly paler than rest of underbody, which mostly dark blue-grey, with light grey scaling or mottling across breast and upper belly and much broader pale fringing on lower belly, vent and flanks (which appear light grey with some darker blue-grey mottling); undertail-coverts light brown-grey; undertail light brownish-grey; iris dark brown to red-brown; bill and legs black. Sexes alike in plumage, male larger than female. Juvenile undescribed. VOICE. No information; not heard to vocalize during 15 observations from late Nov to early Dec.

Habitat. Interior and edge of closed, humid tropical submontane forest. Type locality a sphagnum bog c. 500 m in diameter surrounded by mossy forest of moderate stature (20–25 m) dominated by gymnosperms (e.g. *Dacrydium*, *Dacrycarpus*) and montane angiosperms (e.g. *Nothofagus*, *Lithocarpus*). Known only from above 1150 m.

Food and Feeding. Predominantly frugivorous: seen repeatedly to forage in middle and upper levels of vegetation, especially at plants producing small fruits. Not wary.

Breeding. No evidence of reproductive behaviour during late Nov and early Dec, when two individuals had non-enlarged gonads. In Oct 1979 or Jan–Feb 1981, a *Melipotes* nest found in Foja Mts was described as a bundle of debris 20 cm in diameter and woven around trunk of sapling at height of 9 m; was attributed to *M. fumigatus*, but present species seems to be only member of genus in Foja Mts.

Movements. No information; probably sedentary.

Status and Conservation. Not assessed. Appears not to be globally threatened. Although not yet listed, this is a restricted-range species, confined to North Papuan Mountains EBA. First observed in Nov 2005, and formally described as recently as 2007. Common within tiny known global range. Habitats of this species apparently not at risk: entire Foja Mts massif is apparently without roads, with few or no trails, and no villages except on lowland fringes; further, local people do not enter the uplands, partly because they are not easily accessible but also because the summits are considered sacred.

Bibliography. Beehler *et al.* (2007), Diamond (1985).

Genus MACGREGORIA De Vis, 1897

85. MacGregor’s Honeyeater

Macgregoria pulchra

French: Méléphage de MacGregor **Spanish:** Mielero de MacGregor
German: MacGregor-Honigfresser

Other common names: Macgregor’s Bird/Lappetface, M(ac)Gregor’s/Orange-wattled Bird-of-paradise, Ochre-winged Honeyeater

Taxonomy. *Macgregoria pulchra* De Vis, 1897, Mount Scratchley, south-east New Guinea. Formerly considered a bird-of-paradise (Paradisaeidae), but molecular analyses indicate that it is a honeyeater, closely related to *Melipotes*. Two subspecies recognized.

Subspecies and Distribution.

M. p. caroliniae Junge, 1939 – discontinuously in Snow Mts and Oranje Mts (Mt Carstenz, Carstenz Meadow, Kemabu Plateau, Mt Wilhelm, L. Habbema) and Star Mts (Mt Capella, Dokfuma Meadow), in W & C New Guinea.

M. p. pulchra De Vis, 1897 – disjunctly on highest peaks of C Owen Stanley Range (Mt Strong–Chapman, Mt Albert Edward, Mt Scratchley, Mt Victoria, Mt Batchelor), in SE New Guinea.

slightly with black remiges; large, conspicuous fleshy orange-yellow wattle in hemicircle around eye, broken at front and with small notch in upper edge (colour of wattle may change; what was thought to be same bird had wattle brilliant orange on one day and duller yellow-orange on next day); iris reddish-brown to red; bill glossy black; legs blue-grey. Sexes alike in plumage, male larger than female and with wattle slightly larger. Juvenile is duller and browner than adult, with iris dark brown (not reddish). Race *caroliniae* has smaller wing and tail than nominate, but weighs significantly more. VOICE. Vocalizes often; sexes maintain contact while foraging by countercalling, apparently having sex-specific calls. Commonest vocalization a rapidly repeated, high-pitched double “jeet” whistle, used as contact and alarm (strange “nyeh nyeh nyeh” possibly this call); a “pscer”

note often given as greeting when one bird returns to roost or perch where other waiting, call repeated many times (associated with wing-flicking and tail-cocking); also a “schweet schweet” call at rate of more than 1 call/second. Other calls include low sharp “click” or double “click”, repeated several times; low plaintive “quee”; soft sharp “chick-chick-chick-chick” or “chick-chick, chick-chick” during aerial chases; weak “psheer”, repeated 2–5 times; and quiet “cheu”, repeated several times. Quiet nasal, slurred “chiff” heard from pair-members together. When a pair was disturbed, larger bird (probable male) uttered loud “krah!” and smaller one (probable female) a “jeet” note; when two individuals were uttering “schweet” notes, a third bird, separated from them, called with “fwooiip”. Wingbeat noise conspicuous whirring, whining or rustling or low loud hollow sound; during glides, outstretched wings (widely spread tips of primaries) make continuous “zing-g-g-g” sound, though glides can also be silent.

Habitat. Subalpine woodland and forest, including patches within alpine grassland, dominated by two gymnosperms, the podocarp *Dacrycarpus compactus* (an important foodplant) and *Libocedrus papuanus*; in at least one site, *Dacrycarpus* was the single dominant tree species forming canopy. Distribution apparently limited by distribution of *Dacrycarpus*. Occupies both forest interior and ecotones between forest and grassland or other habitats; recorded also in subalpine shrubland and forest at edge of Carstenz Meadow. From 2700 m to 4000 m, most commonly 3200–3500 m.

Food and Feeding. Appears highly specialized, but not well known. Primarily frugivorous; almost certainly takes arthropods, and possibly forages at flowers. Preferred food fleshy resin-rich fruit (7–8 mm in diameter) of *Dacrycarpus compactus*, which periodically superabundant, but fruiting of this species unpredictable and not always annual (fruiting cycle appears to be very long, with periods of more than a year with no ripe fruit in local populations of the plant); when *Dacrycarpus* unavailable, range of other fruits taken include *Eurya brassii*, *Cladomyza acrosclera*, *Styphelia suaveolens*, *Coprosma divergens*, *Astelia alpina*, *Rapanea* (including *R. involucreata*), *Symplocos cochinchinensis*. Reported not to take *Dacrycarpus compactus* fruits when available, but it is suggested that this was because the fruit was unripe (once they appear, fruits take about a year to ripen). Forages mainly in canopy, but also at all levels of forest, including on ground, and on small prostrate or cushioning shrubs, in low shrubs and in subcanopy trees; observed to forage among moss and other epiphytes and in foliage. Suggested as probably using open-bill probing (“Zirkeln”), inserting closed bill into a substrate such as moss or soft wood, then opening bill to allow better access to food. Confiding and conspicuous; more wary when on ground. Active, but described also as somewhat sluggish; seen to hop actively about perches while flicking tail and wings; can remain in small area for several hours at a time. Most often in twos (probably pairs), also recorded singly, in threes (possibly adults and offspring) or fours, or in small parties. At Dokfuma (Star Mts), one pair thought to have range c. 1 km long and several hundred metres wide, and may have been territorial, once chasing a third individual from area; in other studies, however, no intraspecific territorial behaviour observed, despite fact that birds appeared to occupy discrete areas. Seen to chase a parrot (Psittacidae) from a food tree.

Breeding. Breeding apparently about Jul to Feb, with eggs possibly mid-Jul to mid-Aug; cycle seems mostly tied to unpredictable fruiting of main foodplant (*Dacrycarpus compactus*), but breeding

recorded also when virtually no such fruit available. Appears to maintain permanent pair-bond, partners remaining together all year. Only three nests described, each an open, bulky cup, exterior mainly of moss, plant stems, lichens, and few sticks, lined with slender stems and small leaves (lining thick at top of walls, thinner at base), cup of one also contained many leaves and phyllodes, for two nests external diameter 24 cm and c. 31.5 cm, depth 19 cm (both), internal diameter 13 cm and 13.5 cm, depth 9 cm (both); placed high in tree, two nests 11 m and 15 m above ground, one in multiple upright forks in emergent tree in moss forest, other supported in upright small branches growing from small lateral branch; once rebuilt within 50 m of old nest, and suggested that may build at or near sites used in previous years. Single known clutch, of 1 egg; incubation of egg and brooding of young apparently by female only, brooding evidently ceased when nestling 11–12 days old; at one nest both sexes fed chick, though male did more, at least during brooding period; no information on duration of incubation and nestling periods, but chick development appears slow (nestling has well-developed wattle like that of adults). Remains of one found in stomach of Eastern Marsh-harrier (*Circus spilonotus*).

Movements. Possibly largely sedentary, but considered also partial or local nomad or migrant. Movements (and breeding) tied to unpredictable fruiting of main foodplant, and species can be absent from areas when fruit not available; left one site during long period when *Dacrycarpus compactus* not fruiting, and has been absent from area around L Omha (SE New Guinea) for periods of as long as one year.

Status and Conservation. VULNERABLE. CITES II. Restricted-range species: present in Central Papuan Mountains EBA. Common above 3000 m in Star Mts, where Ketengban people protect it for cultural reasons; rare on Mt Albert Edward (in Wharton Ranges), where only one record since 1933. May be in slow but ongoing decline. Patterns of movements, combined with dependence for food and possible breeding on unpredictable fruiting of *Dacrycarpus compactus*, may mean that populations fluctuate periodically and dramatically. Occupied range estimated at less than 1000 km², even though overall distribution extends from W Papua E to SE New Guinea; occurs in patchy and geographically restricted habitat, probably with little or no interchange between isolated populations. Absent from large areas of apparently suitable habitat in Central Highlands, suggesting past extirpation in these areas, possibly in part through hunting pressure. Hunted as game in parts of range, particularly as it is large, confiding and conspicuous (and site-faithful), and therefore easy to kill; threat from hunting is exacerbated by the species’ small fragmented population. Hunters visiting upper fringes of montane forest to hunt wallabies (Macropodinae) in alpine grasslands build a hide beneath favoured fruiting tree (usually *Dacrycarpus compactus*) and kill one to several honeyeaters as they come to roost or forage. Although much of its range is remote and inaccessible to hunters, new roads are creating access to its habitats; subalpine habitats are also under threat from global warming. Protected by law throughout range.

PLATE 45

Family MELIPHAGIDAE (HONEYEATERS) SPECIES ACCOUNTS

Genus *SUGOMEL* Mathews, 1922

86. Black Honeyeater

Sugomel nigra

French: Myzomèle cravaté **German:** Trauerhonigfresser **Spanish:** Mielero Blanquinegro
Other common names: Gray's Honeyeater, Charcoal Bird

Taxonomy. *Myzomela nigra* Gould, 1838, interior of New South Wales, Australia. Genus sometimes subsumed in *Certhionyx*; species formerly placed in *Myzomela*. Genus name is neuter, because ends in a neuter Latin noun. Monotypic.
Distribution. Australia from W coast E, largely S of c. 19° S, to W slopes of Great Divide; typically absent from larger desert regions (e.g. Simpson Desert), Nullarbor Plain, and moister coastal and subcoastal areas of SW, S & SE.

Descriptive notes. 10–13 cm; male 9.5–11 g, female 8.5–12 g. Male is strikingly pied, with head, neck and upperparts mostly black and underbody mostly white, black of throat and upper breast continuing as V on lower breast and as narrow scruffy black stripe down centre of belly; upperwing-coverts and remiges black-brown, remiges with fine grey edges in fresh plumage; undertail black, underwing blackish-brown; iris black-brown; bill and gape black; legs black to grey-black. Female is slightly smaller than male, plumage very different: mainly dark grey-brown above and white below, with small diffuse whitish patch above and behind eye, whitish malar area finely mottled grey-brown and extending as white stripe along side of

throat, and whitish chin and throat densely mottled dark grey-brown; breast variable, from streaked with dark grey-brown at side to heavily mottled dark grey-brown in centre and grading to dark grey-brown patch at side; uppertail and most of upperwing slightly darker than upperbody, blackish-brown, larger secondary coverts with off-white to pale grey-brown fringes, remiges with fine pale grey edges, undertail black-brown, underwing dark brown; bill black, creamy cutting edge on base of lower mandible and creamy gape, rest of bare parts as male. Juvenile is very like female, but throat and upper breast more uniform grey-brown, secondary coverts and tertials of upperwing have clear pinkish-buff fringes when fresh (more scaly appearance of folded wing), remiges and rectrices finely edged pinkish-buff, and gape yellow. Voice. During breeding, male gives two-note whistle, "pee-pee", in display-flight, also distinctive high-pitched plaintive "peeee" repeated for long periods from perch. Other calls include metallic "chick chick", by both sexes after hatching of eggs; harsh scolding notes; "chirrup" sometimes interspersed among whistles; weak squeaking by female during distraction display.

Habitat. Arid and semi-arid low, open woodlands and shrublands, often dominated by *Acacia*, especially mulga (*Acacia aneura*), or by mallee eucalypts, and typically with shrubby understorey of emu-bush (*Eremophila*) or, less often, *Grevillea*, paperbarks (*Melaleuca*) or *Acacia*; also low open sclerophyllous woodlands dominated by eucalypts, including bloodwoods (*Corymbia*) or Darwin woollybutt (*Eucalyptus miniata*), or woodland dominated by cypress-pine (*Callitris*) or casuarina, or mixed *Eucalyptus*–*Callitris*–*Melaleuca* woodland. Sometimes in spinifex (*Triodia*) savanna, especially where flowering shrubs present, or in chenopod shrublands.

Food and Feeding. Nectar (particularly of emu-bush, but also wide range of other plants) and small insects. Forages in shrubs, in crowns of trees, mostly eucalypts, and in mistletoe (*Loranthaceae*). Obtains nectar by probing flowers, sometimes sally-hovering to do so. Insects caught mostly by sally-striking in air (up to 15 m from perch), birds often searching while perched on top of shrubs; also gleaned from bark. Observed to eat charcoal and ash at extinguished fires; groups of up to ten seen at sources of ash or charcoal. Usually singly, in twos (probably pairs) and in small parties; sometimes in large flocks at food sources, e.g. 110 individuals in two small clumps of *Eremophila longifolia* within c. 100 m². Often with other species in and around flowering plants.

Breeding. Jul–Dec, mostly Aug–Nov, possibly starting and finishing slightly earlier in W Australia; also Mar in Queensland; apparently single-brooded. Often in loose groups or colonies. Both members of pair appear to choose nesting site, but only female carries material and builds, accompanied by male (male may carry material during selection process); nest a shallow open cup (can become flattened as young grow) of fine twigs, grass and other plant material, lightly bound with

spider web, lined with soft grass and rootlets and, less often, plant fibre, bark and other soft materials, construction starts with foundation of spider web around fork of branch, on to which twigs placed and secured with more web, external diameter 5–8 cm, depth 3.8–6.4 cm, internal diameter 3.8–4.5 cm, depth 2–2.5 cm; usually attached to horizontal fork of low shrub or tree, sometimes in angled or near-vertical fork or growth and often quite exposed (occasionally on fallen timber), usually close to ground at 0.3–1 m (mean of 45 nests 0.67 m), but reported extremes of 15 cm and 2.5 m. Clutch usually 2 eggs, rarely 1 or 3, mean 1.91; incubation mainly or solely by female, sometimes shared more equally by both sexes, 14–16 days, once 13 days for 1-egg clutch; chicks brooded and fed by both sexes, female doing more of brooding, male may do more feeding, nestling period 15–16 days; fledglings seen with both parents, but one brood fed only by male. Nests parasitized by Horsfield's Bronze-cuckoo (*Chrysococcyx basalis*).

Movements. Generally considered migratory, with seasonal trends in numbers in a given area; suggestion that range expands into S inland in spring, and contracts to N inland in late summer, extent of expansion varying annually and dependent on overall population of species, with tendency for movement through much of C Australia. Tends to be recorded in S & E of range more often in spring–summer than in autumn–winter; appearance or numbers at many sites, however, unpredictable and species frequently described as nomadic (although many such claims based merely on sporadic occurrences at locations, particularly at periphery of range). Broad-scale analysis of data in E Australia found strong evidence of movements, but with no clear pattern. Occurrence at edge of normal range often irregular, and irruptions widely recorded. Widely scattered records outside main range, e.g. in N Western Australia (N Kimberley Division), Top End of Northern Territory and E coast. Movements often related to flowering of foodplants, especially emu-bush and mistletoe; possibly some movements made in response to seasonal conditions, including drought. Numbers at any site may also reflect annual changes in size of total population. Said possibly to move in groups, and flock of at least 1000 in Feb at one site possibly gathering before N movement.

Status and Conservation. Not globally threatened. Widely but sparsely distributed, and locally common. Recorded densities of 0.07–1.08 birds/ha. May be adversely affected by loss of *Eremophila* through grazing and through control measures where this considered a weed by pastoralists.

Genus MYZOMELA Vigors & Horsfield, 1827

87. Drab Myzomela

Myzomela blasii

French: Myzomèle sobre **German:** Amboinahonigfresser **Spanish:** Mielero Apagado
Other common names: Drab/Amboina/Ambon Honeyeater, Amboina/Ambon/Seram Myzomela

Taxonomy. *Stigmatopis blasii* Salvadori, 1882, Ambon, Moluccas.
Forms a superspecies with *M. albigula*, *M. eques*, *M. cineracea* and *M. obscura*. Monotypic.

Distribution. Seram, Boano and Ambon, in S Moluccas.

Descriptive notes. c. 11.5 cm; 12–17 g. Top and side of head and neck and upperbody greyish-olive, slightly greyer on rump, with diffuse darker loreal stripe and narrow eyering, stripe continuing a short distance behind eye; upperwing and tail subtly darker olive than upperbody, somewhat duller on remiges, fine olive edges on remiges and rectrices; chin and throat whitish-grey with darker feather centres (scaly appearance); underbody pale yellowish-grey; at least some individuals have trace of reddish on forehead and throat; iris brown; bill black; legs grey-blue. Sexes alike, male probably larger but no data. Juvenile undescribed. **VOICE.** Undescribed.

Habitat. Lowland and montane forest; in one study, single records in unlogged forest and in logged forest. From 150 m to 2200 m, mainly 600–700 m.

Food and Feeding. Forages at flowering trees for nectar (particularly of *Eugenia*); presumably also takes small invertebrates. Mainly in canopy; on Seram, seen to forage in crowns of tall flowering trees. Inconspicuous, easily overlooked. In small flocks of 10–20 individuals in flowering trees.

Breeding. No relevant information.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA. Uncommon or common on Seram; scarce or common in Manusela National Park. Only recently recorded from Boano.

Bibliography. Bowler & Taylor (1989a, 1993a, 1993b), Coates & Bishop (1997), Diamond *et al.* (1989), Isherwood *et al.* (1998), Koopman (1957), Marsden (1998), Schönwetter & Meise (1981), Sibley & Monroe (1990), Stresemann (1914a), White & Bruce (1986).

88. White-chinned Myzomela

Myzomela albigula

French: Myzomèle à menton blanc **German:** Weißkinn-Honigfresser **Spanish:** Mielero Barbiblanco
Other common names: White-chinned/White-throated Honeyeater, White-throated Myzomela

Taxonomy. *Myzomela albigula* E. J. O. Hartert, 1898, Rossel Island, Louisiade Archipelago, New Guinea.

Forms a superspecies with *M. blasii*, *M. eques*, *M. cineracea* and *M. obscura*. Two subspecies recognized.

Subspecies and Distribution.

M. a. pallidior E. J. O. Hartert, 1898 – Bonvouloir Is (Hastings I, East I), Conflict Group (including Panasesa), Deboyne Is (including Panapompom) and Kimuta I, in W & C Louisiade Archipelago, off SE New Guinea.

M. a. albigula E. J. O. Hartert, 1898 – Rossel I, in E Louisiade Archipelago.

Descriptive notes. 13–14 cm; male 16.3 g, one female 13 g. Male nominate race is fairly uniform dark brownish-grey above, paler brownish-grey below, with indistinct red wash on centre of forehead and crown, ruby-red streak on chin and centre of throat, and diffuse dusky streaking on breast; iris brown; bill black; legs bluish-grey. Female is like male but smaller, with chin and throat contrastingly pale greyish-white, and red throat stripe less distinct. Juvenile undescribed. Race *pallidior* is much paler, with white throat paler than that of either sex of nominate. **VOICE.** Undescribed.

Habitat. No information; thought to be forest.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Data-deficient. Restricted-range species: present in Louisiade Archipelago EBA. Very poorly known, but considered not globally threatened; thought to be common. Apparently not present, or no longer present, on Misima and Tagula, despite some statements to the contrary.

Bibliography. Anon. (2007a), Beehler *et al.* (1986), Butchart & Stattersfield (2004), Coates (1990), Diamond *et al.* (1989), Koopman (1957), LeCroy & Peckover (1998), Rand & Gilliard (1967), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

89. Red-throated Myzomela

Myzomela eques

French: Myzomèle à menton rouge **German:** Dolchstich-Honigfresser **Spanish:** Mielero Barbirrojo
Other common names: Red-throated/Ruby-throated/Red-spot Honeyeater, Ruby-throated/Red-spot(ted)/Red-chinned Myzomela

Taxonomy. *Cinnyris eques* Lesson and Garnot, 1827, Waigeo, West Papuan Islands, off north-west New Guinea.

Forms a superspecies with *M. blasii*, *M. albigula*, *M. cineracea* and *M. obscura*. Often treated as conspecific with *M. cineracea*. Four subspecies recognized.

Subspecies and Distribution.

M. e. eques (Lesson & Garnot, 1827) – West Papuan Is (Waigeo, Salawati, Misool) and NW New Guinea (Vogelkop and Onin Peninsula).

M. e. primitiva Stresemann & Paludan, 1932 – N New Guinea from Geelvink Bay E to Astrolabe Bay.

M. e. nymani Rothschild & E. J. O. Hartert, 1903 – S & E New Guinea (E from Vogelkop–Mimika R on S coast and from Huon Gulf on N coast).

M. e. karimuiensis Diamond, 1967 – Karimui, in Eastern Highlands (E New Guinea).

Descriptive notes. 14 cm; mean 13.8 g (nominate), male average 15.8 g and female 12.4 g (*nymani*). Male nominate race is wholly blackish-brown, slightly paler below, with glossy red to scarlet patch on chin and throat, faint red spot on forehead; underwing light grey-brown with diffusely darker trailing edge and tip; iris light brown to golden-brown; bill black; legs dark grey. Female is like male but smaller, somewhat paler and duller, dark brown to dark grey-brown, slightly warmer brown on rump and uppertail-coverts, and often lacks red frontal spot; remiges have faintly paler brown outer edges. Juvenile undescribed; immatures similar to female but slightly paler and greyer, wholly dusky brownish-grey, slightly paler below, with varying faint or non-existent red wash on forehead and cheeks, and poorly defined gular stripe. Race *primitiva* is darker than nominate, with smaller red throat patch; *nymani* male is more grey-toned than others, with more extensive red throat patch covering whole chin and throat; *karimuiensis* considerably darker than others, with deeper red throat patch, also slightly longer tail. **VOICE.** High-pitched “chip” typical of genus, given occasionally; heard to give a series of musical chirps that developed into sibilant twitter when two birds chasing each other and displaying.

Habitat. Primary rainforest, forest edge and tall secondary forest and regrowth; at Lakekamu, found in lowland alluvial rainforest and edge. Sea-level to 500–600 m, but recorded locally to 1200 m.

Food and Feeding. Primarily nectar, from wide range of flowering plants, including Myrtaceae and figs (*Ficus*); also insects, and reported as eating figs growing from tree trunks. Forages mainly in outer canopy of tall flowering trees, also in vines and epiphytes (seen to visit inflorescences of canopy epiphyte *Schefflera*); mostly in upper canopy (to 24–46 m above ground), less often in lower canopy, subcanopy, middle storey and, occasionally, substage layers. Of nine observations of foraging at Karimui, six in upper canopy and rest in lower canopy. Often forages on flowering sago (*Metroxylon*). Main techniques gleaning and probing. Less active than congeners. Often in gatherings of up to 20–30 birds in flowering trees, frequently with other honeyeaters, including congeners such as *M. nigrita*, *M. adolphinae* and *M. cruentata*, and parrots such as Red-flanked Lorikeets (*Charmosyna placensis*); less often singly or in twos (probably pairs). Readily associates with mixed-species flocks.

Breeding. Nest with young in late Mar; breeding in E of range thought to end late Jul to early Aug, and breeding in W several months later. Nest an untidy and rather scanty cup made of strips of strong black arboreal lichen, suspended from fork of leafy branchlet; one was 3 m above ground near top of sapling, c. 15 cm from trunk, and well concealed by foliage. No other relevant information.

Movements. Resident, possibly territorial, but appears to disperse locally to exploit flowering trees.

Status and Conservation. Not globally threatened. Generally uncommon in lowland forest in E Sepik District and at Crater Mt (in Chimbu Province); considered common elsewhere. At Brown R

density less than 1 bird/ha. In all foraging groups most individuals appear to be males, suggesting either skewed sex ratio or sexual difference in foraging behaviour.

Bibliography. Anon. (1978a), Bailey (1992), Beehler *et al.* (1995), Bell (1982a, 1982c, 1984b), Brown & Hopkins (1996), Coates (1990), Diamond (1967, 1972a), Diamond *et al.* (1989), Finch (1978, 1980b, 1983), Gilliard & LeCroy (1966), Gregory (1995b), Hartert (1930), Hicks (1992), Koopman (1957), Murray (1988b), Ogilvie-Grant (1915), Pearson, D.L. (1975), Rand (1942a, 1942b), Rand & Gilliard (1967), Richards & Suryadi (2002), Ripley (1964), Rowland (1995), Schönwetter & Meise (1981), Stein (1936), Terborgh & Diamond (1970), Tolhurst (1991), Weston (1976b).

90. Ashy Myzomela

Myzomela cineracea

French: Myzomèle cendré **German:** Schlichthongfresser **Spanish:** Mielero Cenizo
Other common names: Ashy/Bismarck/Cinereous Honeyeater, Grey/Bismarck/Umboi/Selater's Myzomela

Taxonomy. *Myzomela cineracea* P. L. Selater, 1879, New Britain.

Forms a superspecies with *M. blasii*, *M. albigula*, *M. eques* and *M. obscura*. Often treated as conspecific with *M. eques*. Birds from Umbui, slightly larger (and male possibly slightly paler above) than those of New Britain, described as race *rooki*, but differences considered too slight to warrant recognition of geographical races. Monotypic.

Distribution. Umbui and New Britain, in Bismarck Archipelago.

Descriptive notes. 14.5–16 cm; male average 15.6 g, female 12.2 g. Male is dark brown to dark greyish-brown above, slightly darker, black-brown, on tail, and with faint fine paler brown fringes on some upperwing-coverts (most noticeable on greater), and fine olive to brown edges on most remiges; some have diffusely darker, dusky forehead, lores or eyering; rosy patch on chin and throat; below paler, pale grey-brown, becoming even paler on vent and undertail-coverts; undertail brownish-grey, underwing white with diffuse silvery brownish-grey trailing edge and tip; iris brown to reddish-brown; bill black; legs grey to blue-grey. Female is smaller than

male, with small rose-pink patch on chin and centre of throat. Birds looking much as adult but with orange gape and brown head are possibly juveniles, but confirmation needed; immature apparently like female, with rosy patch on chin and throat. **Voice.** Calls infrequent, quiet and unobtrusive. Regular series of single or double notes often at dawn, "chip-chip-chip" or "chip-chop, chip-chop"; rapid harsh chattering "chee-chee-chee...", rising and falling in pitch; thin whistled "hoet, hoet".

Habitat. Most lowland habitats that provide cover, including primary rainforest, forest edge, secondary forest and regrowth, and other modified habitats such as gardens and coconut plantations. Sea-level to 1200 m or more.

Food and Feeding. Diet includes nectar and insects. Forages from canopy to understorey, mainly in canopy and substages, in flowering trees, coconut palms and low shrubs. Usually seen singly; sometimes associates with other species, including other honeyeaters, in flowering trees; on Mt Uali (c. 900 m), seen to forage with congeners *M. cruentata* and *M. erythromelas*.

Breeding. Season appears to be second half of dry season and middle of wet season; eggs late Jul, early Oct and early Jan to late Feb. Nest a thin-walled bowl or cup made of fine stems, roots and fibres from leaf sheaths, internal diameter 4 cm, depth 3–7 cm, suspended from fork of shrub or small tree. Clutch usually 2 eggs. No other relevant information.

Movements. No information; probably resident, with local movements.

Status and Conservation. Not assessed. Probably not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. Widespread in lowlands and foothills; considered moderately common to abundant.

Bibliography. Bishop & Jones (2001), Coates (1990), Coates & Peckover (2001), Diamond *et al.* (1989), Dutton (2007a), Eastwood (1995b), Eastwood & Gregory (1995), Eastwood *et al.* (1997), Finch & McKean (1987), Fletcher (2000a), Gilliard & LeCroy (1967b), Hartert (1930), Koopman (1957), LeCroy & Peckover (1983), Mayr (1955), Mayr & Diamond (2001), Orenstein (1976), Schönwetter & Meise (1981), Stattersfield *et al.* (1998), Storey & Eastwood (1991).

91. Dusky Myzomela

Myzomela obscura

French: Myzomèle ombré **German:** Rußhönigfresser **Spanish:** Mielero Sombrio
Other common names: Dusky/Moluccan Honeyeater, Moluccan Myzomela; Red-brown Honeyeater/Myzomela (*rubrobrunnea*)

Taxonomy. *Myzomela obscura* Gould, 1843, Port Essington, Northern Territory, Australia.

Forms a superspecies with *M. blasii*, *M. albigula*, *M. eques* and *M. cineracea*. Races fall into two groups, nominate, *harterti*, *fumata*, *rubrobrunnea* and *aruensis* comprising "nominate group" and other three the "simplex group". Birds on Pulu Adi (SW New Guinea) of uncertain racial identity; provisionally included in *fumata*. Proposed race *munna* from NE Australia (Cape York, in N Queensland) is synonymized with *harterti*. Eight subspecies recognized.

Subspecies and Distribution.

M. o. mortuana E. J. O. Hartert, 1903 – Morotai, off N Halmahera.

M. o. simplex G. R. Gray, 1861 – Halmahera, Ternate, Tidore, Kasiruta, Bacan and Damar (N Moluccas).

M. o. rubrotincta Salvadori, 1878 – Obi and Bisa, in N Moluccas.

M. o. fumata (Bonaparte, 1850) – New Guinea from S Vogelkop (S from Sorong) E along S coast, including Pulu Adi (off Triton Bay), to Trans-Fly and Milne Bay and, in SE, on N coast E from near Popondetta; also islands of N Torres Strait (probably Boigu and Sabai).

M. o. rubrobrunnea A. B. Meyer, 1874 – Biak I, in Geelvink Bay (NW New Guinea).

M. o. aruensis Kinnear, 1924 – Aru Is.

M. o. harterti Mathews, 1911 – islands of C & S Torres Strait, and NE Australia (coastal and subcoastal Queensland from Cape York Peninsula S to Moreton Bay).

M. o. obscura Gould, 1843 – Tiwi Is (Bathurst I, Melville I) and N Northern Territory (Arnhem Land), in N Australia.

Descriptive notes. 13–15 cm; male 11.8–15.1 g and female 10–12.3 g (nominate), male 11.8–17.5 g, female 9–12.5 g and sexes combined 9.5–15 g (*harterti*), two birds 12 g (*fumata*). Nominant race dark grey-brown above, slightly darker on lores, and merging to paler and greyer-tinged brown on side of head, chin and throat, breast and upper belly, and to slightly paler and greyer on rest of underbody; in close view, most have indistinct dull dusky stripe in centre of throat, and some have very faint and diffuse maroon wash on forehead and forecrown (and sometimes very faintly over more of face, chin

and throat); upperwing and uppertail slightly darker than upperbody, secondary wing-coverts with faint light brown fringes and, in fresh plumage, remiges with fine pale grey edges (become duller with wear); undertail and underwing dark grey-brown, slightly paler on underwing-coverts and with thin pale edges on basal inner webs of remiges; iris dark brown to grey-brown; bill black, gape varies (possibly seasonally) from black to pale yellow; legs slate-grey, blue-grey or brown or black. Sexes alike in plumage, male slightly larger than female. Juvenile is very like adult, but rump and uppertail-coverts slightly paler and warmer brown than rest of upperbody,

secondary coverts have broader and paler tips giving more patterned appearance to folded wing (sometimes forming subtle wingbar), secondaries thinly edged dull olive, bill blackish with obvious paler yellowish base of lower mandible, and gape yellow and swollen. Races differ little, mainly in tone of plumage and prominence of dusky centre of throat: *harterti* is darker and less grey than nominate, dusky patch or stripe on throat more distinct; *fumata* is like nominate but darker, with fainter or no dusky marking on throat, also reported as variable, birds of mangroves being darker than others (study needed); *aruensis* is darker and browner again than previous, especially below; *simplex* has reddish or rufous edges on remiges and rectrices, and some pinkish-brown fringes on breast feathers; *rubrobrunnea* is darker than nominate, with brownish-red wash in plumage and reddish throat stripe; *mortuana* is also dark, with strong red tinge on breast; *rubrotincta* has red wash on back, wings and tail, and pink wash on abdomen. **Voice.** In Australia, usual call a short mournful whistle or single note, often repeated; on Obi, a thin high "sut-sit, sut-sit, sut-sit". Song described as squeaking warble, or jumble of squeaky, high-pitched notes, "tip-tip-eeee-chip", third note longer and descending. Other calls include soft trilling chatter; scolding notes; quiet "tick, tick"; and upslurred squeaky "seet" or "sweet". Continuous twittering during mutual chasing in small flocks; said to give excited "see, see" notes during chases.

Habitat. In Australia, mainly dense coastal or lowland rainforests and monsoon forests, also in such habitats at higher altitudes; often in rainforests with *Ficus* in canopy, and sometimes emergent eucalypts or paperbarks, and with thick middle storey of various tree species and generally sparse ground cover. Also riparian forests, especially of weeping paperbarks (*Melaleuca leucadendra*), often mixed with eucalypts; open eucalypt or open to closed paperbark woodlands and forests, especially when in flower, and often with tall or dense understorey of sclerophyllous shrubs; ecotone between monsoon forest and open eucalypt forest; and mangroves. Sometimes in towns, and parks and gardens, and locally in coconut plantations; rarely, in heathland. In New Guinea, mangrove forest, monsoon woodland (in Trans-Fly Region), savanna woodland, coastal scrub and scrubby savanna, forest edge bordering grassland, secondary growth, open areas, and in villages and town gardens (e.g. in Port Moresby). In Wallacea, mainly in primary forest and tall secondary forest, including edges. In Wallacea sea-level to at least 450 m on Halmahera, 1200 m on Bacan and at least 800 m on Obi; in New Guinea mainly coastal, from sea-level to c. 100 m, commonly to 600 m or more on Sogerit Plateau. In Australia sea-level to tablelands, e.g. at 750–800 m on Atherton Tableland (N Queensland). In W Torres Strait, found only on those islands where *Lichmera indistincta* absent.

Food and Feeding. Little known outside Australia. Mainly nectar, some arthropods (insects, spiders). Nectar taken from wide variety of plants over year; near Darwin, fed at flowers that provided best sources of nectar. Spends much time in eucalypts, and in New Guinea attracted to flowering sago palms (*Metroxylon*). Arboreal, usually foraging among flowers and foliage in upper and middle canopy, but also at lower levels, down to near ground. In NE Queensland, tended to feed slightly higher in wet season than in dry season; and in Northern Territory, when feeding on nectar in Kakadu National Park, some indication that foraging height varied seasonally. Forages much among foliage (e.g. more than 60% of feeding observations in Northern Territory and NE Queensland), particularly outer foliage; also on branches of trees, branches and trunks of shrubs, dead leaves and vines, and in air. Probes flowers for nectar; gleans and probes for insects among twigs and leaves and from bark and branches; obtains insects also by flutter-chasing, and by sallying, sally-striking and sally-hovering, and once seen to glean from spider web. Active, often hanging upside-down. Usually singly or in pairs, sometimes in small parties (e.g. of up to six individuals) or congregates in flowering trees; sometimes forages in mixed-species flocks, often with other meliphagids. Chases Black Sunbirds (*Leptocoma sericea*).

Breeding. Poorly known. In Australia breeding recorded in most months, with eggs May, Jul, Sept and Nov and nestlings and fledglings Mar–Dec; in New Guinea Jun, Sept and Apr, with nestlings mid-Sept, fledglings Sept (and nestlings or fledglings mid-Apr), and "breeding" specimens Jan, Mar–Apr and Oct–Dec (most Nov–Dec). Nest a small, frail, thin-walled cup made of grass, thin strips of paperbark, rootlets, plant tendrils and plant down, with spider web (mostly around rim), lined with fine grass or long hair, external diameter 6–7 cm, depth 4–5 cm, internal diameter 3–4 cm, depth 3–8 cm; suspended by rim from branch of tree 0.3–1.5 m (mean 4–5 m) up, usually near end of branch and among dense foliage, one was suspended between three vertical branches of small tree, nests recorded in paperbark, eucalypt, occasionally mangrove, sometimes in ornamental or fruit tree in garden. Usual clutch 2 eggs; no information on incubation and nestling periods; adults continue to feed young after fledging.

Movements. Not well known. Primarily resident in most of range. Some dispersive or local ("nomadic") movements apparent in Australia, including on some islands in Torres Strait (Booby, Badu and Saibai), and considered occasional visitor to some areas, such as Darwin (Northern Territory) and Blackall and Conondale Ranges (SE Queensland); around Rockhampton (Queensland), movements may be more seasonally regular. In New Guinea also occasional visitor at some sites, indicating probable local movements or dispersal.

Status and Conservation. Not globally threatened. Moderately common in Wallacea; fairly common in New Guinea; locally common in Australia. Reports from Misool (West Papuan Is) and, in Australia, from Groote Eylandt and near Borroloola (Northern Territory) and in New South Wales considered doubtful. In Australia, recorded densities 0.06–0.64 birds/ha. Abundance in Kakadu National Park (Northern Territory) negatively correlated with damage caused by water buffalo (*Bubalus bubalis*), although buffalo now in reduced numbers and no longer a threat. In Lamb Range (NE Queensland), significantly more abundant in regrowth rainforest 20–30 years old than in mature rainforest. On Halmahera, the people of Jailolo consider present species to be young of *Melittograis gilolensis* (the two often forage together).

92. Red Myzomela

Myzomela cruentata

French: Myzomèle vermillon **German:** Bluthonigfresser **Spanish:** Mielero Rojo
Other common names: Red Honeyeater, Red-tinted Myzomela/Honeyeater

Taxonomy. *Myzomela cruentata* A. B. Meyer, 1874, Arfak Mountains, north-west New Guinea. Races fall into two groups: "n nominate group" (with *coccinea*) of New Guinea and New Britain, and "*erythrina* group" (remaining four races) of New Ireland and satellite islands. Six subspecies recognized.

Subspecies and Distribution.

M. c. cruentata A. B. Meyer, 1874 – New Guinea, including Yapen I (in Geelvink Bay).
M. c. coccinea E. P. Ramsay, 1877 – New Britain and Duke of York Is, in Bismarck Archipelago.
M. c. lavongai Salomonsen, 1966 – New Hanover.
M. c. erythrina E. P. Ramsay, 1877 – New Ireland.
M. c. vinacea Salomonsen, 1966 – Djaul I, off NW New Ireland.
M. c. cantans Mayr, 1955 – Tabar I (in Tabar Group), off NE New Ireland.

Descriptive notes. 11–13 cm; male average 8.6 g, female average 7.9 g. Male nominate race appears almost entirely bright, glossy crimson, brightest on rump and uppertail-coverts, duller on back; uppertail dark brown with strong crimson suffusion, crimson edges of rectrices; upperwing dark brown, coverts with broad crimson tips and fringes, tertials with strong crimson suffusion, remaining remiges with crimson outer edges (folded wing appears dusky red); undertail brown; underwing light grey-brown, coverts paler and (on at least some) mottled off-white; some individuals have faint crimson-brown mottling above and

below, but not certain whether this is an immature character or the result of wear; iris rufous-brown to blackish-brown; bill black to brownish-black, gape yellow; legs dusky grey to blackish-brown, soles yellowish. Female is smaller than male, drab brown to olive-brown, slightly paler and greyer below, especially in middle of belly and vent, with diffuse red wash on forehead, chin and throat, and on rump, uppertail-coverts and uppertail; bare parts as for male. Juvenile is very similar to female, but wing shorter and gape swollen; immature male like adult female, but red wash more extensive (reaching varying to hindworn, nape and back), also varying washed red below, especially on chin and throat and centre of breast, and retains juveniles remiges and rectrices. Races differ in intensity of red of male (complicated by effects of wear), in "*erythrina* group" also in plumage of female (very similar to respective adult male) and juvenile: *coccinea* is very like nominate but a little smaller, with slightly longer bill, male slightly paler and duller red, female with slightly more extensive and deeper rose-red on forehead, throat and rump to uppertail-coverts; *erythrina* is slightly larger than nominate, male much duller and darker red, with almost blackish crown, female like male but duller red above and slightly paler below, juvenile has red wash on upperparts, chin and throat and (on most) paler red wash on breast and belly (young male slightly brighter red on throat, contrasting more with breast, than young female); *lavongai* male is larger than previous, with brighter and glossier red upperparts (more like nominate), female undescribed, juvenile like that of previous but with buff-grey breast and abdomen; *cantans* male is similar in size to previous and larger than *erythrina*, but upperparts darker and duller red than both, female undescribed, juvenile much darker than *erythrina*, dark red above, bright red chin and throat, strongly contrasting red-washed dark grey-brown underparts; *vinacea* is much larger than other races, male plumage as that of *lavongai*, female almost identical to *erythrina* but possibly slightly darker and duller below, juvenile very different from that of all other races, dark plum-red, slightly paler below, chin and throat contrasting only slightly with underbody. **Voice.** Typically quiet. Main call a high-pitched "tseet" at rate of c. 1 per 5–10 seconds, or (New Guinea) a high-pitched insect-like "tzip" or "tick" repeated frequently at intervals of several seconds; other calls include repeated high "sit" during mutual chasing.

Habitat. Primary rainforest and forest edge and tall secondary growth (regrowth forest); recorded also in savanna eucalypt woodland at Varirata National Park (New Guinea); common in gardens, plantations and secondary forest on New Hanover. Altitudinal range varies among islands, and on New Britain and New Ireland associated with presence of congeners. In New Guinea mainly in hills between c. 750 m and 1600 m, but visits foothills and occasionally adjacent lowlands (down to at least 400 m); several recorded at 1200 m and 1500 m in Fakfak Mts, and recorded in lower belt of mid-mountain forest at 1370–1460 m in Telefomin region; in Vanapa–Veimauri region (in SE), fairly common above 210 m but scarce at lower levels and only occasionally on lowland plains. On New Britain, where *M. erythromelas* occupies lowlands, present species found only in mountains above 900–1100 m and up to at least 1720 m; on New Ireland *M. pulchella* occupies mountains, with present species (which thought to be the more recent invader) restricted to lowlands and hills from sea-level to 900–1000 m, mainly below range of congener (in recent surveys, however, present species recorded regularly at 1175 m but *M. pulchella* on only one day at this altitude). New Britain also supports larger *M. cineracea*, which co-exists with both congeners there owing to differing ecology.

Food and Feeding. Nectar; also small arthropods, mainly insects. Seen to visit inflorescences of *Poikilospermum*, *Albizia* and the canopy epiphyte *Schefflera*; in New Guinea visits sago palms (*Metroxylon*), and on New Ireland forages in flowering coconut palms. Mainly in canopy of forest, and most often in flowering trees. In Whiteman Range (SW New Britain), foraged through abundant clusters of red flowers in canopy of forest on summit ridge, probing to base of flowers from all angles, sometimes reaching down or hanging to do so; one foraged in one small area for c. 5 minutes. Where no flowering present, seen to search foliage rapidly for arthropods. Forages mainly by probing and gleaning. In Nakanai Mts (EC New Britain), usually seen while sally-hovering to take nectar from flowers, but also probed large cushions of moss hanging from tree branches. Described as quiet and inconspicuous; in Bismarcks usually seen singly or in small parties, foraging quietly at flowers in crowns of tall forest trees. Also congregates with conspecifics, other meliphagids and other species; at Mt Uali (New Britain) foraged with *M. cineracea* and *M. erythromelas*.

Breeding. Breeding birds in Feb–Apr. No other information.

Movements. Probably largely sedentary, but some local movements or dispersal. Descends to foothills and lowlands to feed on flowering trees. Resident S New Ireland. In E New Guinea, possibly resident at Crater Mt but suggested that it may leave area during periods of low nectar availability (perhaps Dec–Mar); considered feeding visitor or vagrant in lowland and foothill forest around Port Moresby. **Status and Conservation.** Not globally threatened. Generally scarce to moderately common, locally common. Described as abundant (at least 100 pairs/km²) in some places.

Bibliography. Beehler (1978a, 1980b), Beehler & Alonso (2001), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Bell (1969, 1982a, 1984b), Berggy (1978), Bishop & Jones (2001), Brown & Hopkins (1996), Clapp (1987a), Coates (1990), Diamond (1972a), Diamond *et al.* (1989), Eastwood (1995b, 1996b), Finch (1980b, 1983), Finch & McKean (1987), Fletcher (2000b), Gibbs (1994), Gilliard & LeCroy (1961, 1967a, 1967b), Gregory (1995b), Hartert (1930), Jones & Lambley (1987), Koopman (1957), Leavesley & Leavesley (2000b), LeCroy & Peckover (1983), Mack & Wright (1996), Mackay (1980), Mayr (1955), Mayr & Diamond (2001), Mayr & Rand (1937), Murray (1988b), Ogilvie-Grant (1915), Rand (1942b), Rand & Gilliard (1967), Rothschild *et al.* (1932b), Salomonsen (1966b), Sclater (1879), Terborgh & Diamond (1970), Weston (1976b).

93. Black Myzomela

Myzomela nigrita

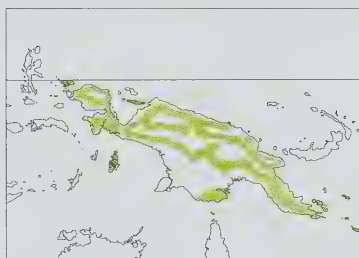

French: Myzomèle noir **German:** Mohrenhonigfresser **Spanish:** Mielero Negro
Other common names: (Papuan) Black(ened)/Carbon Honeyeater, Blackish/Carbon/Papuan Black/White-sided Myzomela

Taxonomy. *Myzomela nigrita* G. R. Gray, 1858, Aru Islands.

In past, treated as conspecific with *M. pammelaena* and *M. tristrami*. Six subspecies recognized.

Subspecies and Distribution.

M. n. steini Stresemann & Paludan, 1932 – Waigeo I, in West Papuan Is.
M. n. pluto W. A. Forbes, 1879 – Meos Num I, in Geelvink Bay.
M. n. meyeri Salvadori, 1881 – Yapen I and W, N & E New Guinea.
M. n. nigrita G. R. Gray, 1858 – Aru Is and SC New Guinea (Eilanden R E to Fly R).
M. n. forbesi E. P. Ramsay, 1880 – D'Entrecasteaux Archipelago (Goodenough I, Fergusson I, Dobu I), off SE New Guinea.
M. n. louisiadensis E. J. O. Hartert, 1898 – Louisiade Archipelago (Woodlark I, Misima I, Tagula I), E of D'Entrecasteaux.

Descriptive notes. 10–12 cm; male 8.3–10.8 g (all races except *steini* and *pluto* combined), two males 9 g and 10.5 g (nominate), male 9–11 g and three females 8.3–9 g (*meyer*). Male nominate race is wholly glossy black, except for white axillaries and largely white underwing with silvery grey-brown trailing edge and tip; iris brown to light brown; bill black, thin yellowish gape on at least some (possibly immatures); legs dark grey, sometimes tinged yellow, soles yellow. Female is smaller than male, plumage olive-brown to grey-brown, paler below, with reddish to rosy wash on forehead, lores, anterior cheek, and chin and upper throat. Juvenile undescribed;

immature male appears to vary, some with head, neck and upper breast black with few scattered olive-brown flecks (particularly on hindneck), merging to largely black body strongly mottled with light olive-brown (particularly on scapulars and underbody), and with brown-tinged black upperwing and tail, others entirely black except for small area of rose-red on chin, some like adult female (and doubtfully distinguishable in field), yet others apparently dark brown to grey-black with dull red to rufous forehead (possibly also chin and throat), study needed; immature female doubtfully separable from adult in field. Races differ in plumage tone and pattern and in size: *meyer* is larger than nominate (male wing 57–64 mm, nominate 55–58.5 mm), male plumage as nominate, female dimorphic, either like male but duller black or like female of nominate; *forbesi* is larger than previous, male less glossy than nominate and with conspicuous red patch on hindworn to nape, female like nominate but red of forehead extends to crown; *pluto* is much larger than others (wing 63.5–68.6 mm), male plumage like nominate, female resembles female of *meyer*; *steini* male is like adult female; insufficient data available on *louisiadensis*. **Voice.** Main call a dry, high-pitched "sit" or "zeet", given often, and incessantly by flocks in flowering trees; also a rather formless series of "sit" and "see" (called "song"). Vocalizations of race *meyer* described as twittering and sibilant.

Habitat. Hill and lower montane primary forest, forest edge and tall secondary growth; also in eucalypt savanna woodland in Trans-Fly, and monsoon forest in parts of range. Throughout range mainly in foothills and lower mountains, between c. 500 m and 1000 m, but recorded also in lowlands in Trans-Fly region (e.g. near sea-level on Oriomo R) and Aru Is, and visitor to lowlands elsewhere; occurs locally up to 1250 m, e.g. at Mafulu. On Goodenough I occupies lowlands, and not recorded above 620 m.

Food and Feeding. Nectar and small arthropods (insects), occasionally berries. Specialist of upper part of crowns of flowering trees. Of 77 observations in flowering trees in Karimui area, 94% in upper half of canopy and only 6% in lower half. Sometimes descends to lower levels at forest edge. Visits flowering trees in savanna; also visits flowering sago palms (*Metroxylon*), e.g. at lowland sites at Brown R. Seen to probe inflorescences of *Albizia*, *Astronia*, *Syzgium* and *Poikilospermum*. Often gathers in small parties in flowering trees, where frequently associates with other meliphagids and other bird species, especially parrots such as Red-flanked Lorikeet (*Charmosyna placensis*), Black Berrypecker (*Melanochoris nigra*) and Dwarf Longbill (*Oedistoma iliolophus*); at Mafulu, feeds with congeners in *Albizia* trees.

Breeding. Female with possible nesting material seen chased by a male in late Jul (middle dry season), six "breeding" specimens in Mar–Apr. No other information.

Movements. Mainly resident, but moves locally. Moves from foothills to lowlands to exploit flowering trees, e.g. suggested that it may regularly visit lowland forest at Brown R to forage; occurs in small numbers in Vanapa–Veimauri lowlands when trees in flower, but often absent when no flowering.

Status and Conservation. Not globally threatened. Locally common throughout range. Black-plumaged birds seen far more than brown-plumaged individuals, indicating a possible bias in sex ratio or differences in ecology or behaviour between sexes.

Bibliography. Anon. (1978a), Beehler (1978a), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Bell (1982a, 1984b), Brown & Hopkins (1996), Coates (1990), Coles (1976a), Diamond (1972a, 1976), Diamond *et al.* (1989), Eastwood (1989a), Finch (1978, 1980b, 1983), Gilliard & LeCroy (1967a), Gregory (1995b), Hartert (1930), Hicks (1992), Koopman (1957), LeCroy & Peckover (1998, 1999), Mack & Wright (1996), Mayr & Rand (1937), Melville (1979), Murray (1988b), Ogilvie-Grant (1915), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Rothschild *et al.* (1932b), Stein (1936), Terborgh & Diamond (1970), Weston (1976b).

PLATE 46

Family MELIPHAGIDAE (HONEYEATERS) SPECIES ACCOUNTS

94. New Ireland Myzomela

Myzomela pulchella

French: Myzomèle de Nouvelle-Irlande

Spanish: Mielero de Nueva Irlanda

German: Neuirland-Honigfresser

Other common names: New Ireland/Olive-yellow Honeyeater, Crimson-fronted/Olive-yellow Myzomela

Taxonomy. *Myzomela pulchella* Salvadori, 1891, New Ireland.

Relationships uncertain. Monotypic.

Distribution. New Ireland, in E Bismarck Archipelago. To date, only recorded from S of island, but presence in C considered probable.

Descriptive notes. 11 cm; 10 g. Forehead, crown, anterior ear-coverts, malar area and chin to uppermost breast are red, forming conspicuous red mask enclosing narrow black loreal stripe that extends in thin ring around eye; upperparts dark grey-brown to dark olive-brown, greater upperwing-coverts and secondaries with fine olive-green outer edges; red below grades to slightly dusky red on upper breast; rest of underbody pale buff to dirty yellowish-white, with diffuse band of dark streaking across lower breast bordering dusky red; iris dark grey to dark brown; bill black, possibly blackish-brown in some; legs blue-grey, soles yellowish. Sexes alike in adult plumage (probably differ in size). Juvenile has olive-brown head, neck and upperbody, including face, with scattered red feathers on head and neck and a small patch of red on chin and throat, olive-grey breast, rest of underbody as adult or more olive-yellow. Voice. Call a buzzy, downslurred "bzrr" or repeated "zzr".

Habitat. Montane forest, mainly above 500 m; generally replaced at lower altitudes by *M. cruentata*. Recorded to 1840 m in Hans Meyer Range. In surveys of S New Ireland, however, recorded below 500 m, with records at 150–200 m on eight of nine days at the site; also commonly at 1800 m (on each of six days), but recorded on only one of seven days at 1175 m (where *M. cruentata* recorded on all seven days).

Food and Feeding. No data on diet. Singles and small groups forage in canopy and congregate in flowering trees; two seen to search through epiphytic growth on branch. No other information available.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. In general, present species is very poorly known. No measures or estimates of abundance are available, but species is considered to be generally common above 500 m.

Bibliography. Beehler (1978b), Beehler & Alonso (2001), Coates (1990), Diamond *et al.* (1989), Dutson (2007a), Finch & McKean (1987), Koopman (1957), Mayr & Diamond (2001), Stattersfield *et al.* (1998).

95. Rotuma Myzomela

Myzomela chermesina

French: Myzomèle de Rotuma German: Karmesinhonigfresser Spanish: Mielero de la Rotuma

Other common names: Rotuma Honeyeater

Taxonomy. *Myzomela chermesina* G. R. Gray, 1846, no locality = Rotuma Island, Fiji.

Forms a superspecies with *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. rubratra*, *M. cardinalis* and possibly also *M. erythromelas*. Limits of this superspecies are not certain and require further investigation, especially regarding possible inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group, *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species considered a race of *M. cardinalis* by some authors. Monotypic.

Distribution. Rotuma and offshore islets, including Uea, in N Fiji.

Descriptive notes. 13 cm. Adult male is striking: largely black, with broad bright red to scarlet strip down centre of upperbody (centre of mantle and back, and rump and uppertail-coverts), and bright red to scarlet chin, throat, breast, side of belly and anterior flanks; scarlet plumage often patchily mottled black, especially on upperbody and breast, belly and flanks; iris brown; bill black; legs grey-black. Female is like male but duller, with less red: head and upperparts grey-black, and red of upperbody duller throughout and reduced in extent on mantle to back; underparts much duller, blackish-brown chin to upper breast

with weak red wash (sometimes stronger red blotching on upper throat), merging to brownish-grey or brownish-black on lower underbody, with strong red wash on lower breast and upper belly and, on some, weak rufous tinge on vent and undertail-coverts; upperwing-coverts and remiges have narrow greyish-olive edges. Juvenile not fully described, but said to lack red on upperparts, and wing-coverts apparently edged brownish-olive; immature male has dark areas of plumage duller than adult, red on lower throat and upper breast much reduced (sometimes lacking, in which case reddish of upper throat and that of lower breast and anterior flanks separated by blackish band), belly to lower flanks and undertail-coverts pale cinnamon-grey, wing (probably largely retained juvenile plumage) has coverts edged brownish-olive, remiges edged olive, some have dark reddish wash on forehead and forecrown; immature female like adult female, but dark parts of plumage browner, and underside washed cinnamon or dark rufous. Voice. No information available; apparently undescribed.

Habitat. All habitats on Rotuma, including primary and secondary forest, edges, agricultural gardens and plantations.

Food and Feeding. Nectar; also strongly insectivorous. Gleans from outer branches in forest; seen also to hang from seedheads of weeds in open areas. Sallies for aerial insects. Highly active, aggressive and conspicuous.

Breeding. Recently fledged young in mid-May. Nest and eggs said to be like those of *M. jugularis*. No other information.

Movements. Resident.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Rotuma Secondary Area. Common on Rotuma, where the most abundant bird species. Nearly all native forest on Rotuma has been cleared for agriculture, including plantations, but extensive secondary vegetation exists and appears to provide suitable habitat. Abundance and habitat tolerance of the species should protect it from cyclone damage. Pacific rat (*Rattus exulans*) already present on the island, but introduction of other exotic predators a hypothetical threat.

96. Sulawesi Myzomela

Myzomela chloroptera

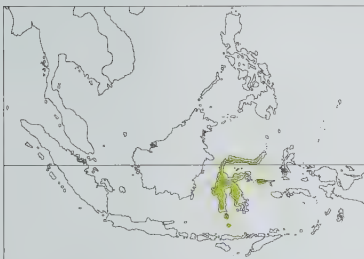

French: Myzomèle des Célèbes **Spanish:** Mielero Rojo de Célebes

German: Sulawesihonigfresser
Other common names: Sulawesi/Celebes Honeyeater, Celebes Myzomela

Taxonomy. *Myzomela chloroptera* Walden, 1872, Menado, north Sulawesi. Forms a superspecies with *M. chermesina*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. rubratra*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group. *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. wakoloensis* and *M. boiei*. Proposed race *charlottae* (from Latimodjong Mts, in C Sulawesi) considered inseparable from nominate. Birds of this species on Taliabu (in Sula Is) provisionally placed in nominate, but possibly represent an as yet undescribed race. Four subspecies currently recognized.

Subspecies and Distribution.

M. c. chloroptera Walden, 1872 – mountains of N & C Sulawesi, and Sula Is (Taliabu).
M. c. juga Riley, 1921 – S Sulawesi.
M. c. eva Meise, 1929 – Salayar and Tanahjampea (S of Sulawesi).
M. c. batjanensis E. J. O. Hartert, 1903 – Bacan, off SW Halmahera.

Descriptive notes. 9–11.5 cm. Male nominate race is distinctive and striking, with head, neck, breast and mantle to uppertail-coverts scarlet-red, forming broad stripe down centre of upperbody boldly contrasting with black scapulars, wing and tail, and with narrow black loreal stripe extending in thin ring around eye and diffusely for short distance behind eye; neat narrow olive-green edges on remiges; flanks, belly, vent and undertail-coverts pale grey-brown to greyish-white, varying olive-yellow wash on centre of belly; pale flank feathers often show narrowly around angle of folded wing (separating black of wing from

red of head and neck); iris dark brown; bill and gape black; legs dark grey. Female drab brown above, more rufous brown on rump, darker sepia-brown tail and wings, thinly but conspicuously edged yellowish-olive on primary-coverts and flight-feathers, other wing-coverts edged buff; forehead, lores, frontal part of ear-coverts, chin and upper throat flame-red (more orange than in males), merging into light brownish grey on rear ear-coverts, neck sides and lower throat, breast and upper belly; lower belly, vent and undertail-coverts whitish-buff. Juvenile very similar to female; immature male as adult female but tertials, like wing-coverts, broadly edged light buff, not yellowish-olive as in adults, scarlet on head, scattered single scarlet feathers also on upperparts to vent, and on breast; immature female undescribed. Race *juga* is slightly larger than nominate, male differs in brownish-black (not black) scapulars, wing and tail, lacks yellowish wash on belly, female also similar to nominate but flame scarlet on forehead more extended and less rufous brown on upperparts; *eva* differs from nominate only in slight yellowish tinge on belly; *batjanensis* has red of plumage darker and, below, confined to throat, with breast olive, lower underbody off-white to greyish-white. Voice. Very vocal; male calls and sings from exposed branches high in canopy. Calls of nominate race include loud clear “peeew”, repeated every 2–2.5 seconds, while moving in canopy (soft “tschiep...tschiep...” repeated at intervals of several seconds probably the same call); sharp disyllabic “treeu treeé”, second syllable higher-pitched, repeated at 10-second intervals from treetops perch; fast, trisyllabic “tuwéédu” lasting 0.5 seconds and repeated every 2–3 seconds during foraging; and fast, rather brief, thin and high-pitched warble, from treetop (possibly same as short, pleasant, twittering phrase).

Habitat. Mainly primary montane forest and tall secondary forest, including moss forest, possibly mangroves. Recorded also in selectively logged forest in N Sulawesi. Mainly in mountains, but extends to lowlands on low-lying islands: 700–2400 m (occasionally down to 200 m) on Sulawesi; above 800 m on Taliabu; mainly 1500–2200 m on Bacan, but possibly down to 800 m; only in lowlands on Tanahjampea.

Food and Feeding. Nectar from flowers; a subadult was once attracted to an insect light-trap at night. Frequents canopy and upper middle storey; often forages in flowering trees, also in flowering mistletoes (of genus *Loranthus*) and parasitic shrubs. Seen singly, in twos (probably pairs), and either occasionally or regularly in small flocks; often in mixed-species flocks on Taliabu, and occasionally reported in mixed flocks of insectivores on Sulawesi.

Breeding. No information.

Movements. Possibly moves locally to exploit resources.

Status and Conservation. Not globally threatened. Common to scarce. Considered scarce to uncommon on Sulawesi, but common in Lore Lindu National Park. Moderately common on Tanahjampea, and very common on Taliabu.

Bibliography. van den Berg & Bosman (1986), Coates & Bishop (1997), Davidson & Stones (1993), Davidson *et al.* (1995), Dutton (1995), Koopman (1957), Riley (1924), Riley & Mole (2001), Rozendaal & Dekker (1989), Sibley & Monroe (1990), Stones *et al.* (1997), Stresemann & Heinrich (1940b), Watling (1983), White & Bruce (1986).

97. Wakolo Myzomela

Myzomela wakoloensis

French: Myzomèle de Forbes **German:** Wakolohonigfresser **Spanish:** Mielero del Wakolo
Other common names: Wakolo Honeyeater

Taxonomy. *Myzomela wakoloensis* H. O. Forbes, 1883, Lake Wakolo, Buru, Moluccas.

Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. rubratra*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group. *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. chloroptera* and *M. boiei*; has been treated as a race of *M. sanguinolenta*. Races differ in plumage and, apparently, vocally; possibly represent two separate species. Two subspecies recognized.

Subspecies and Distribution.

M. w. wakoloensis H. O. Forbes, 1883 – Buru, in S Moluccas.
M. w. elisabethae van Oort, 1911 – Seram, in S Moluccas.

Descriptive notes. 9–11.5 cm; 7–9 g (*elisabethae*). Male nominate race is predominantly red above and on much of underbody, with fine black loreal stripe extending in thin ring around eye, contrasting largely black scapulars, wing and tail, wing-coverts with scarlet-red edges (smaller coverts appear largely red); much of belly red, vent and undertail-coverts black with red feather edges (appearing mottled); iris dark brown; bill and gape black, brownish base of lower mandible; legs black-grey, olive-grey or yellow-olive. Female is not well described; brown above, merging to slightly paler greyish-brown on side of head

and underbody, and with varying reddish wash on head. Juvenile and immature undescribed. Race *elisabethae* differs from nominate in having narrower scarlet edges on upperwing-coverts, more black below (much of belly to undertail-coverts), and some may have black on lower back or rump (confirmation needed). Voice. Undescribed; variants of vocalizations on Buru and Seram said to differ, but not well studied.

Habitat. Mainly primary forest and tall secondary forest, possibly also mangroves. Mainly in mountains: lowlands to 1500 m, mainly above 800 m, on Buru; 300–1400 m, mainly above 700–900 m, on Seram.

Food and Feeding. Forages at flowers for nectar; presumably also takes small invertebrates. Usually seen singly or in twos (probably pairs), occasionally in small flocks. Often in mixed-species foraging flocks on Buru; only infrequently so on Seram, but observed there in mixed flocks typically including, among others, three species of white-eye (*Zosteropidae*). Seen to forage also with *Lichmera albaauricularis*.

Breeding. No information.

Movements. Possibly locally nomadic.

Status and Conservation. Not globally threatened. Restricted-range species: present in Buru EBA and Seram EBA. Not well known. Described as moderately common to common on Buru and Seram.

Bibliography. Bowler & Taylor (1989a, 1993a, 1993b), Coates & Bishop (1997), Jepson (1993a), Jones *et al.* (1990), Koopman (1957), Marsden (1998), Poulsen & Lambert (2000), Rheindt & Hutchinson (2007a), Stattersfield *et al.* (1998), Stresemann (1914a), White & Bruce (1986).

98. Banda Myzomela

Myzomela boiei

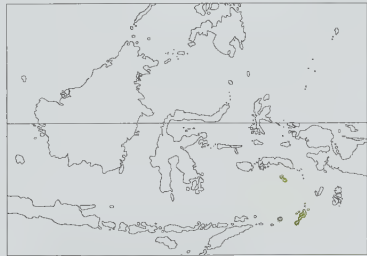

French: Myzomèle de Banda **German:** Inselhonigfresser **Spanish:** Mielero de las Banda
Other common names: Banda/Boie's/Wallacean Honeyeater

Taxonomy. *Nectarinia* (*Myzomela*) *Boiei* S. Müller, 1843, Banda Islands, Moluccas.

Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. sanguinolenta*, *M. caledonica*, *M. rubratra*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group. *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. chloroptera* and *M. wakoloensis*; has also been treated as a race of *M. sanguinolenta*. Two subspecies recognized.

Subspecies and Distribution.

M. b. boiei (S. Müller, 1843) – Banda Is, in S Moluccas.
M. b. annabellae P. L. Sclater, 1883 – Babar and Tanimbar Is (Yamdena, Selaru), in extreme E Lesser Sundas.

Descriptive notes. 9–11.5 cm. Male nominate race is distinctive and striking, with head, neck, upper breast and mantle to uppertail-coverts scarlet-red, forming broad stripe down centre of upperbody boldly contrasting with black scapulars, wing and tail, and with narrow black loreal stripe extending in thin ring around eye; black extends from scapulars to form breast-band across lower breast, separating red of chin, throat and upper breast from greyish-white lower underbody; iris black; bill and gape black; legs brownish. Female is brown above, merging to slightly paler greyish-brown on side of head and underbody, and with vary-

ing reddish wash on head; probably smaller than male. Juvenile and immature undescribed. Race

annabellae male differs from nominate in having narrower black breastband and more olive underbody below it. **VOICE.** Undescribed.

Habitat. Mainly primary closed forest and tall secondary forest, secondary woodland, lightly wooded farmland, selectively logged semi-evergreen forest, cultivation; also mangroves on Yamdena. Only in lowlands in Tanimbar Is.

Food and Feeding. Seen singly, in twos (probably pairs) and, occasionally, in small flocks. No other information.

Breeding. In Banda Is, nests with eggs and with nestlings recorded in Sept, and recently fledged young late Apr. No other information.

Movements. Possibly locally nomadic.

Status and Conservation. Not globally threatened. Restricted-range species: present in Banda Sea Islands EBA. Very poorly known. Described as moderately common in Tanimbar Is.

Bibliography. Bishop & Brickle (1999), Coates & Bishop (1997), Hartert (1901), Johnstone & Sudaryanti (1995), Koopman (1957), Moores *et al.* (1996), Rheindt & Hutchinson (2007a), Stattersfield *et al.* (1998), White & Bruce (1986).

99. Scarlet Myzomela

Myzomela sanguinolenta

French: Myzomèle écarlate **German:** Scharlachhonigfresser **Spanish:** Mielero Escarlata
Other common names: Scarlet/Sanguineous/Blood-(red)/Crimson Honeyeater, Sanguineous Myzomela

Taxonomy. *Certhia sanguinolenta* Latham, 1801, Nova Hollandia = region of Port Jackson, New South Wales, Australia.

Species sometimes referred to by name *M. dibapha* (published with current name simultaneously in same book), but priority of present name has now been stabilized. Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. caledonica*, *M. rubrata*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group, *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. caledonica*. Monotypic.

Distribution. Coastal and subcoastal E Australia from NE Queensland (Cape Melville) S, inland to Great Divide (as far inland to e.g. Carnarvon Gorge and, in New South Wales, Warrumbungle Ranges and Southern Tablelands), to E Victoria (mainly from near Mallacoota W to Mitchell River National Park).

Descriptive notes. 9–11 cm; male 6.4–13 g, female 5.5–10 g. Male is distinctive, with head and neck to upper breast and broad stripe down centre of upperbody scarlet (some have small patches of black scattered throughout scarlet plumage), black loreal stripe continuing in thin ring around eye, and black scapulars, side of mantle and upperwing; greater secondary wing-coverts with fine off-white fringes, and remiges with thin whitish edges (diffuse pale panel on folded wing; pale margins of feathers much reduced with wear); uppertail dull black; underbody below upper breast largely greyish-white with diffuse red wash, dark grey mottling on side of belly, diffuse dark grey patch at side of breast bordered along upper edge by blackish band; undertail dark grey, underwing white with broad dark grey trailing edge and tip; iris dark brown; bill and gape black, gape sometimes pale yellow; legs dark grey or dark grey-brown. Female is smaller than male, has head, neck and upperbody brown, slightly paler and greyer on side of head and merging to pale grey-brown on chin and throat; usually pink-red wash on chin and throat, often also on malar area and anterior ear-coverts, sometimes a faint red-brown wash on forehead (at times with brighter red patches), and sometimes a few small scarlet-red patches on uppertail-coverts; uppertail blackish-brown, all except central feather pair with narrow straw-yellow fringes; upperwing blackish-brown, marginal secondary coverts brown, median and greater coverts and tertials with narrow light grey-brown or cream fringes, remiges with thin straw-yellow edges (diffuse pale panel on folded wing); underbody light brown-grey, browner on breast and paler creamy or off-white in mid-line; underwing and undertail as male, bare parts as male except for yellow basal half or most of lower mandible, yellow gape. Juvenile is very similar to female, but slightly warmer brown above with contrastingly paler brown rump and uppertail-coverts, slightly broader and richer buff-brown fringes on secondary coverts and tertials, pale edges of remiges slightly brighter yellow, gape initially clearly swollen; immature male similar to adult but retains varying amounts of juvenile plumage, some probably inseparable in field, some roughly intermediate between adult male and female; immature female poorly known, doubtfully separable from adult female. **VOICE.** Song rather loud, melodious, tinkling and bell-like, often consisting of phrases of 6 notes, rising and falling erratically or, sometimes, short tinkling twitters. Calls include brisk “chiew-chiew”, by both sexes as contact; brief chirps by female when bathing and preening, and when greeting male; and sibilant squeak by female.

Habitat. Dry open sclerophyll forests and woodlands, usually dominated by eucalypts, sometimes mixed with cypress-pines (*Callitris*), *Angophora* and acacias, and usually with sparse understorey; frequently in riparian vegetation around wetlands and with flowering shrubs, such as paperbarks (*Melaleuca*) and bottlebrushes (*Callistemon*). Also often in wet sclerophyll forest with understorey of rainforest plants; less often in rainforest or mangroves; very occasionally in other habitats, e.g. heathland, low open *Banksia* forest or brigalow (*Acacia harpophylla*) woodland. Regularly in parks, gardens and urban areas.

Food and Feeding. Mainly nectar; occasionally fruit and insects. Nectar mainly from *Eucalyptus*, *Melaleuca*, *Callistemon*, *Banksia* and *Grevillea*, and mistletoes (Loranthaceae). Insects taken include beetles (Coleoptera), flies (Diptera), aphids (of family Aphididae) and larval Lepidoptera. Arboreal, usually forages among flowers and foliage in upper and outer canopy, e.g. in one study 92% of observations involved probing of flowers. Obtains nectar by flower-probing, sometimes sally-hovering; obtains insects by gleanings from foliage, twigs and branches, and by sally-striking in air. In study on New England Tableland (N New South Wales), foraged mostly more than 10 m above ground, and spent 24% of time in feeding when levels of nectar moderate; while feeding on nectar, made mean of 13 probes per inflorescence and spent 18 seconds at each inflorescence; when catching flying insects, made average of 1.94 sallies per minute. Forages singly, in twos (possibly pairs), and in small parties of up to twelve or so individuals; sometimes in larger numbers at profusely flowering plants. At least at times appear to defend feeding territories against conspecifics. When

foraging together, usually displaces conspecifics, landing on or near perch vacated by target of attack, but sometimes chases others.

Breeding. Jul–Jan, apparently earlier in N (Jul records) and season possibly shorter in S, and fledglings once recorded in late May; one pair successfully raised three broods in a season. Nests as solitary pair. Nest may be built by both sexes, but roles can vary; small and cup-shaped, contents sometimes visible through wall, made of fine strips of bark and grass, loosely bound with spider web, usually lined with fine plant fibre, casuarina needles and occasionally rootlets, sometimes unlined, external diameter 5.1 cm, depth 3.8 cm, internal diameter 3.8 cm, depth 2.5–3.2 cm; suspended by rim from horizontal or dangling branch, or supported in upright fork, usually hidden among foliage, c. 1.2 m to c. 25 m (mostly 3–12 m, average 5.6 m) above ground. Clutch 2 eggs, occasionally 3; incubation probably by female only, period 11–12 days; chicks fed by both parents, nestling period 11–12 days; juveniles fed by both parents for at least 10 days after fledging.

Movements. Partly resident and partly migratory, with some local movement or dispersal. Appears to be resident in subhumid NE Queensland; irregular visitor to Paluma Range, Feb–Apr and Sept–Nov, which fits with patterns of migration farther S. At intermediate latitudes (SE Queensland and NE New South Wales) at least partly resident, and part of population migratory; N migration recorded in Mar–Apr, and S passage recorded in Queensland Aug–Oct, with passage through or influx into NE New South Wales and SE & E Queensland in winter. Largely spring–summer breeding visitor in S of range, including SE New South Wales and Victoria. In study in SE Queensland, 1986–1993, a small part of population migratory, arriving Mar–Apr and leaving in Dec, but many recorded on passage: some remained in area for several months; suggested that birds also moved inland during times of peak rainfall in summer. Movements often said to be associated with flowering of foodplants (such movement often described as nomadic), fluctuations in numbers coinciding with flowering of certain trees and shrubs; in SE Queensland study, however, presence or absence of blossom was not main factor, and abundance of this species was negatively correlated with rainfall. Sometimes seen to move in small flocks. In Victoria vagrant W of 147° E.

Status and Conservation. Not globally threatened. Locally common. Recorded densities include 0.01–0.02 birds/ha near Armidale and 0.6 birds/ha on Hawkesbury R, both in New South Wales. As with many other dichromatic species in this genus, sex ratio appears to be male-biased, e.g. ratio of 1.5:1 for netted birds in SE Queensland (neither sex appearing to be more susceptible to trapping); males, however, also much more conspicuous than females in appearance and behaviour.

100. New Caledonian Myzomela

Myzomela caledonica

French: Myzomèle calédonien **German:** Neukaledonien-Honigfresser **Spanish:** Mielero de Nueva Caledonia
Other common names: New Caledonian Honeyeater

Taxonomy. *Myzomela caledonica* W. A. Forbes, 1879, New Caledonia.

Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. rubrata*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group, *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. sanguinolenta*. Monotypic.

Distribution. New Caledonia, including I of Pines.

Descriptive notes. 10–12 cm; two males 7.5 and 8.2 g, two females 6.6 g and 6.9 g. Male is strikingly red, black and cream; head, neck and centre of upperbody deep scarlet, with black loreal stripe extending in thin ring around eye, black scapulars and side of mantle and back and scattered black patches exposed throughout scarlet of upperbody (particularly on rump and uppertail-coverts); uppertail dull black; upperwing black, remiges slightly duller and with thin greyish-white to greyish-olive edges (diffuse panel on folded wing, much reduced with wear); red of head extends down to upper breast, dark grey patch at side and merging to

diffuse red wash on lower breast, anterior flanks and side of belly, where increasingly mottled with grey; rest of underbody creamy white; undertail dark grey, underwing white with broad dark grey trailing edge and tip; iris dark brown; bill black; legs dark grey to dark grey-brown or brownish-green, soles yellow. Female is smaller than male, head and neck brownish-grey, slightly paler and greyer at sides and noticeably paler light grey-brown on chin and throat, usually with distinct reddish-brown forehead, anterior ear-coverts, malar area and chin and throat; upperbody brownish-grey, sometimes a few small reddish patches on uppertail-coverts; uppertail blackish-brown, all except central feather pair with narrow straw-yellow fringes, upperwing blackish-brown, brown marginal secondary coverts, fine light brown or cream fringes on median and greater coverts, fine straw-yellow edges of remiges (diffuse pale panel on folded wing); breast, flanks and belly light brown-grey, with olive-grey mottling on breast, merging to paler dirty white on centre of belly, vent and undertail-coverts; underwing and undertail as male; bare parts as male, but basal half (sometimes most) of lower mandible yellow, gape yellow. Juvenile is like female, but upperparts slightly warmer brown (except rump and uppertail-coverts noticeably paler brown), secondary coverts and tertials have slightly broader and richer buff-brown fringes, pale edges of remiges slightly brighter yellow, yellowish gape initially clearly swollen; immature male usually separable by contrasting mixture of adult-like scarlet-and-black plumage and brownish retained juvenile plumage (appearance somewhat between adult male and adult female), some very like adult male and probably inseparable in field. **VOICE.** Male song a series of short hurried phrases, each usually

of 2–10 notes, e.g. a short dry rattle of identical double notes, “tchu-tchu—tchu-tchu— tchu-tchu...”, or “tch-tchwy-tchwy”. Contact call very short sharp high-pitched single “tsip” notes.
Habitat. Humid forest, including stunted forest on high slopes, and niaouli (*Melaleuca leucadendron*) savanna woodland; also forest edge and in modified habitats such as plantations and gardens. Lowlands and middle altitudes.
Food and Feeding. Primarily nectar; also small arthropods (insects). Forages in all types of flowering trees, including niaouli. Confiding and active, climbing among flowers.
Breeding. Breeds Nov–Jan. Nest a tiny and rudimentary cup, made of fine twigs, rootlets and other plant fibres, usually or always unlined, internal diameter 4.5–5 cm, typically attached to branches

by spider web, often high in tree. Clutch 2 eggs; said that parents share incubation and brood-feeding duties; no information on duration of incubation and nestling periods.
Movements. No information; apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species; present in New Caledonia EBA. No estimates of global abundance; variously considered common or rare. Widespread within tiny range.
Bibliography. Delacour (1966), Doughty *et al.* (1999), Dutson (2007a), Hannecart & Létocart (1980), Higgins *et al.* (2001), Koopman (1957), Layard & Layard (1882), Myers (2004), Ross (1988), Stattersfield *et al.* (1998), Stokes (1980), Tristram (1879).

PLATE 47

Family MELIPHAGIDAE (HONEYEATERS)
SPECIES ACCOUNTS

101. Micronesian Myzomela

Myzomela rubrata

French: Myzomèle de Micronésie

Spanish: Mielero de Micronesia

German: Mikronesienhonigfresser

Other common names: Micronesian (Cardinal) Honeyeater; Guam/Safford's Cardinal Honeyeater (*saffordi*)

Taxonomy. *Cinnyris rubrata* Lesson, 1827, Kosrae, east Caroline Islands.

Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. cardinalis* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group, *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. cardinalis*, but differs in morphology and vocalizations. Birds of this species recorded on Sapwuahfik (Ngatik), near Pohnpei, of uncertain race; provisionally included in *dichromata*. Seven subspecies recognized.

Subspecies and Distribution.

M. r. asuncionis Salomonsen, 1966 – N & C Northern Mariana Is (Maug Is and Asuncion S to Anatahan).

M. r. saffordi Wetmore, 1917 – S Northern Marianas (Saipan, Tinian, Aguijan, Rota; formerly also Guam).

M. r. kobayashii Momiyama, 1922 – nearly all islands of Palau (from Kayangel S to Angaur).

M. r. kurodai Momiyama, 1922 – Yap, in W Caroline Is.

M. r. major Bonaparte, 1854 – Chuuk Is, including Nama, Losap and Mortlock Is (Namoluk, Ettal, Lukunor and Satawan atolls), in C Carolines.

M. r. dichromata Wetmore, 1919 – Pohnpei and nearby Sapwuahfik Atoll (Ngatik), in E Carolines.

M. r. rubrata (Lesson, 1827) – Kosrae, E of Pohnpei.

Descriptive notes. c. 13 cm; male 10.5–18 g, female 10.4–15 g (*saffordi*). Male nominate race is striking, with head and neck to breast and belly and central upperbody (centre of mantle and back, and rump and uppertail-coverts) brilliant deep scarlet to scarlet-red, narrow black loreal stripe continuing in narrow ring around eye and as short diffuse blackish stripe behind eye; black bases of red feathers can show through scarlet plumage as patchy black mottling, particularly on mantle, back and scapulars (can appear largely black), but scarlet of upperbody strikingly conspicuous in flight; rest of mantle and back, scapulars, upperwing and uppertail black, remiges with fine pale olive-grey outer edges; vent and undertail-coverts duller, sooty black, undertail dark grey-black; iris brown to dark brown; bill black; legs greyish-black to dark grey-brown. Female is smaller than male, similarly patterned but duller overall, with hood and central upperbody dull red, rest of upperbody, upperwing and uppertail dark brownish-grey to olive-brown, paler olive-grey outer edges of remiges and rectrices, and lower underbody dark grey to olive-grey; bare parts apparently as for male. Juvenile nominate not fully described, juvenile *saffordi* male brownish-olive to brownish-

on chin, throat and central upperbody, with belly to undertail-coverts washed buff. Races differ mainly in general plumage tone and pattern of female, also in tone of red and extent of black on head of male, and in size: *dichromata* is slightly smaller than nominate but with longer bill, male slightly paler scarlet, with broader black loreal stripe and eyering, female duller than nominate, largely dusky brownish-grey, with red reduced to pale wash on upperbody and chin to breast (red on crown to hindneck and side of head lacking or very faint); *kobayashii* is smaller than previous but with slightly longer tail, male like nominate but with darker scarlet-red coloration, and olive edges on remiges and rectrices, female like previous but red darker, head partly red, belly to undertail-coverts and axillaries buff-grey; outer edges of remiges and rectrices pale olive; *kurodai* is apparently smaller than nominate, from which male differs in less intensely scarlet plumage, female dark olive-brown above, slightly paler on chin to upper breast, ashy white with yellowish tinge on rest of underbody, and with red wash on head to breast and centre of upperbody (brightest on back to rump), and olive edges on remiges and rectrices; *saffordi* is slightly smaller than nominate but with longer bill, male like nominate but paler, more orange-red, and edges of remiges and rectrices olive, female like nominate but paler overall, upperparts dark olive-grey and mottled with scarlet, outer edges of remiges and rectrices greenish-olive, lower underbody buff-grey; *asuncionis* male is like previous but slightly larger, female quite different from previous, dark olive-brown above with dull red forehead, nape and chin, red wash on throat, and red back to upper-tail-coverts (but not hindneck and mantle), and underbody pale greyish-yellow, with reddish wash on breast (continuous with chin and throat); *major* is slightly smaller than nominate but with longer bill, scarlet slightly less intense, female like nominate but underbody more intensely red, and lower underbody black, also tail slightly darker. Voice. Fairly vocal, and vocalizations given throughout day, though most vocal at dawn. On Guam, main call a sharp, wheezy, upslurred whistle, typically followed by a chirp, repeated regularly. Song a long, complex series of chirps, tweets and whistles, usually in paired syllables, given for short time before dawn but sometimes also at dusk; in Palau, said to sing only before dawn. On Guam, where apparently extinct, territorial song was described as high-pitched and reedy, given during breeding season. Other calls include wheezy chirps or soft scratchy or wheezing notes, buzzy notes, whistles, and scolding notes; male may utter brief and quiet staccato notes during apparent courtship-flight. Possibly some geographical variation in vocalizations, some phrases apparently heard on only one island, but samples small and study needed.

Habitat. Forest, forest edge, mangroves, native palm (*Clinostigma*) forests, coastal scrub (including *Pemphis*) and strand vegetation, secondary growth, shrubby or weedy savanna, and other disturbed habitats, including coconut plantations and groves, agroforest, roadsides; also in towns and villages, and gardens in urban areas. In Mortlock Is (Chuuk), encountered in all terrestrial habitats: coconut (*Cocos nucifera*) forest, with breadfruit (*Artocarpus*) a co-dominant in coconut forest in interior of islands, coastal scrub or thicket dominated by *Tournefortia* and *Scaevola* or by *Pemphis*, and human-maintained taro (*Colocasia*) patches. In Palau and Northern Mariana Is, and on islands of Sapwuhfik Atoll, more common at forest edges, forest openings and other disturbed habitats than in undisturbed forest; in Marianas, sometimes visits flowering herbaceous plants in open grassy savanna. On Pakin Atoll (Pohnpei), in coconut forest and *Pemphis* scrub. On Yap, Chuuk, Pohnpei and Kosrae most abundant in mangroves, and on Kosrae highest densities recorded in massive trees of mature *Sonneratia* forest and less abundant in usually smaller *Rhizophora*; densities in mangroves, however, varied markedly among islands, possibly as a result of maturity and richness of stands, floristic composition, and competition with other bird species. In S Northern Marianas (race *saffordi*), density variation from island to island possibly related to habitat, species preferring native forest and diverse secondary vegetation (most abundant on Aguijan and Rota, corresponding to highest densities of myzomelids) over homogenous stands of *Leucaena* (common on Tinian and Saipan, where densities lowest); on Saipan, densities in native forest lower than those in disturbed sites. On uninhabited Sarigan (C Northern Marianas), density found to be significantly higher in native forest than in coconut forest, and highest in native forest on island plateau where many *Erythrina* trees were flowering. Sea-level to highest peaks, primarily in lowlands (the overwhelming altitude within species' range): in E Caroline Is, recorded at about same rates below 200 m as at 200–800 m on Pohnpei, and on Kosrae density at 0–100 m about three times greater than at 400–600 m (probably owing to scarcity of nectar in scrubby montane forests at higher elevations).

Food and Feeding. Nectar; also small invertebrates, mainly insects, including aphids (Aphidoidea) and scale insects (Coccoidea), also spiders (Araneae), and in Palau reported as taking snails (Gastropoda). Estimated ratio of nectar to insects 60:40 in one study. Forages at all levels in shrubs and trees; in forest and coconut groves mainly in upper canopy, whereas in more open habitats (including gardens) tend to forage at all levels. Frequently feeds at flowers of coconut palms and native palms and, where present, lantana (*Lantana camara*); seen also to feed at flowers of bananas, *Elaeocarpus*, *Hibiscus*, *Erythrina*, *Cestrum*, *Morinda*, *Premna*, *Scaevola*, *Vitex*, *Cynometra*, *Pemphis*, *Albizia*, *Cassia*, *Schefflera*, *Cyrtandra*, and mangroves (including *Sonneratia*, *Rhizophora*). Moves among flower clusters and systematically inserts bill into every flower, feeding at as many as 30 flowers per minute; spends up to 30 minutes in searching and foraging at single coconut palms in flower. Perches beside, or sometimes hovers at, flowers to take nectar. Gleans invertebrates from foliage or spider webs, and sometimes takes insects by sallying in air; seen to seize spiders and insects from beneath eaves or canvas awnings of buildings. Active and conspicuous, darting among vegetation. Usually singly or in twos, and more often in pairs in breeding season, though sometimes congregates at sources of abundant nectar, e.g. 15 or more in flowering *Parinarium*. Aggressive and territorial; two or three individuals often seen in aerial chases above or through canopy, and even between small islands, and sometimes grapple in mid-air. Defends feeding territory from other small birds, especially white-eyes (Zosteropidae).

Breeding. Throughout Micronesia breeding appears to occur in all months through year, with little or no seasonal fluctuation: in Northern Marianas breeds throughout year, with no evidence of

seasonality, eggs recorded Jan–Mar and May–Jul and nestlings Apr; thought to breed throughout year in Caroline Is, on Chuuk in nearly all months (eggs Jan–Jun, Sept and Dec), on Pohnpei eggs recorded Jul–Sept and one brood Nov–Dec, on islands of Sapwuhfik Atoll many in pairs May–Jul and active nesting in early Jun, on Ant Atoll fledglings in boreal summer, and on Kosrae eggs recorded late Feb and mid-Mar. Territorial; aggressively defends nest against conspecifics and other species. Nest a light, loosely woven (eggs often visible through base or side) but fairly deep cup made of fine grasses, fern fronds, casuarina needles, rootlets, leaves and leaf fragments, plant stems, shreds of coconut bast, and spider web, lined with lichens or fine grasses, on Chuuk cup often made from dark vine tendrils and what appeared to be aerial rootlets or saprophytes, three nests on Saipan made of vine tendrils and *Casuarina equisetifolia* needles (one with part of *Pandanus* leaf skeleton entwined around base); on Guam external diameter 3.5–8 cm, depth 5–12 cm, internal diameter 2.5–6 cm, depth 2.5–5 cm, three nests on Saipan had mean external diameter 6.6 cm, depth 5.5 cm, internal diameter 4.7 cm, depth 4.1 cm, and for 18 nests on Chuuk mean external diameter 5 cm and depth 2 cm; suspended and possibly sometimes supported, often only weakly attached, usually woven into thin horizontal fork at end of branch (sometimes in crotch or close to trunk), typically in dense foliage of small live tree or shrub (including young coconut), and usually less than 5 m above ground, in Marianas generally 1.2–4.6 m (but seven nests on Saipan 1.5–5.1 m, mean 2.9 m; two on Guam were at 3.1 m and 4.6 m), in Palau one c. 2 m up, in Sapwuhfik Atoll one at c. 5 m, but an unfinished nest in Chuuk was 16 m above ground in dead tree. Clutch usually 2 eggs, less often 1 (and brood of three once reported in Palau); incubation and brooding said to be by both sexes, but on Saipan (race *saffordi*) only female incubated and single observation of female brooding, although both parents usually observed close to nests; on Saipan, incubation period 12 days and nestling period more than 13 days, two young leaving nest prematurely at 13–14 days (one chick was returned to nest by observer, subsequently left nest at 15–16 days). Of seven nests on Saipan, three fledged at least one young.

Movements. Resident; possibly some short local movements associated with flowering events. On Kosrae, seen to fly singly or in small flocks, well above canopy, apparently from roosts in coastal lowlands towards foraging sites at higher elevations in inland forests.

Status and Conservation. Not globally threatened. Restricted-range species: present in Mariana Islands EBA, in Palau EBA, in Yap Islands EBA, and in East Caroline Islands EBA. Common to abundant throughout much of range; less so in Marianas, although still one of the commonest bird species there. Many estimates of total population and densities. In C Northern Marianas, race *asuncionis* the most abundant forest bird on Sarigan, with estimated population of 1821 individuals, at overall density of 11.2 birds/ha (although densities differed significantly between surveys in 1990 and 1997). In S Northern Marianas, *saffordi* common to abundant from Saipan S to Rota, with estimated total population for these four islands 63,120 individuals, island densities ranging from 1.14 to 5.70 birds/ha; densities on Saipan declined between surveys in 1986 and 1997, but not known whether this apparent decline is real and, if it is, what the causes for it are. Race *kobayashii* in Palau considered common on all islands, with total population in 1991 estimated at 59,690 individuals, and densities ranging from 0.4 to 3.37 birds/ha. Yap race *kurodai* common, with population of 109,360 individuals at estimated density of 10.98 birds/ha. Race *major* abundant on all islands surveyed in Chuuk Lagoon, with estimated total population of 165,440 birds at mean density of 20.67 birds/ha; the second most numerous landbird in Mortlock Is, where equally abundant on inhabited and uninhabited islands. In Pohnpei, race *dichromata* one of the most abundant bird species, with estimated total population of 358,070 individuals at mean density of 10.71 birds/ha, although a reduction in encounter rates was evident between 1983 and 1994 (but not known whether or not this represents a real decline); density on Ant Atoll 2.7 birds/ha and on Pakin Atoll (where the most numerous bird species) 3.8 birds/ha; common to very common on islands of Sapwuhfik Atoll, with overall density of 1.8 birds/ha. Nominative race restricted to Kosrae (E of Pohnpei), where one of the most abundant birds, with a total estimated population of 136,360 individuals and a mean density of 14.33 birds/ha; in Kosrae mangroves recorded at 40 birds/ha, one of the highest densities of any forest bird in Micronesia. Ready use by this species of modified habitats suggests little immediate impact of increasing human population and development of forestry and agricultural activities. Introduced brown tree-snake (*Boiga irregularis*), however, a major threat to avifauna of all Micronesian islands and already responsible for extirpation of present species on Guam (where deforestation probably caused earlier declines); Guam population declined rapidly in 1970s, almost extinct in S by 1976, and estimated to number fewer than 150 pairs in 1977; last recorded on Guam in 1986. Small numbers of this snake may have become established on Saipan, where same race as that of Guam (*saffordi*) could be at risk. Further, although this species utilizes a wide range of modified habitats, these may not provide suitable nesting sites. On islands of Sapwuhfik Atoll, hunted for food by people, and less abundant on permanently inhabited Ngatik than on other more sparsely populated islands. Often killed by children with slingshots or air-rifles around human habitation. As one of the few nectarivorous species in Micronesia, and owing to its abundance, it may be an important plant-pollinator. As with some other members of genus, sex ratio appears biased at some sites, but this possibly a result of sexual differences in behaviour and conspicuousness (males typically more conspicuous than females) or in foraging levels.

102. Cardinal Myzomela

Myzomela cardinalis

French: Myzomèle cardinal **German:** Kardinalhonigfresser **Spanish:** Mielero Cardenal
Other common names: Cardinal Honeyeater, Black-bellied Honeysucker; Samoan Cardinal Myzomela (*nigriventris*); Lifou Cardinal Myzomela (*lifuiensis*)

Taxonomy. *Certhia Cardinalis* J. F. Gmelin, 1788, Tanna Island, Vanuatu. Forms a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. rubrata* and possibly *M. erythromelas*. Limits of this superspecies not certain and require study, especially regarding inclusion of *M. erythromelas*; further, *M. erythrocephala*, *M. dammermani*, *M. kuehni* and *M. adolphinae* are closely related to the group, *M. vulnerata* also may be, and possibly *M. rosenbergii* and the *M. lafargei* superspecies should be included. Present species sometimes treated as conspecific with *M. chermesina*; formerly treated as conspecific with *M. rubrata*, but differs in morphology and vocalizations. Race *pulcherrima*

apparently a recent invader on San Cristobal (Solomon Is), possibly hybridizing with *M. tristrami* in the past. Eight subspecies recognized.

Subspecies and Distribution.

- M. c. sanfordi* Mayr, 1931 – Rennell, in S Solomon Is.
- M. c. pulcherrima* E. P. Ramsay, 1881 – San Cristobal, Ugi and Three Sisters Is, in SE Solomons.
- M. c. sanctaecrucis* F. Sarasin, 1913 – islands of Santa Cruz Group, including Nepani, Reef Is (Fenualoa, Lonlom), Duff Is, Nendo, Utupua, Vanikoro, and Torres Is (Hiu, Loh).
- M. c. tucoptiae* Mayr, 1937 – Tucopia I (E of Vanikoro), in Santa Cruz Group.
- M. c. tenuis* Mayr, 1937 – Banks Is and N & C Vanuatu (S to Efate).
- M. c. cardinalis* (J. F. Gmelin, 1788) – S Vanuatu (Erromango, Tanna, Aniwa, Futuna, Anatom).
- M. c. lifuensis* E. L. Layard & E. L. C. Layard, 1878 – Loyalty Is (Ouvéa, Lifou, Maré).
- M. c. nigriventris* Peale, 1848 – Samoa (Savai'i, Upolu and offshore islets of Apolima, Manono and Nu'utele) and W American Samoa (Tutuila).

Descriptive notes. 9–12.5 cm; male 16–23 g and female 13 g (*sanfordi*), male 14–18 g and female 11.5–14 g (*pulcherrima*), male 11.5–15 g and female 10–11.7 g (*nigriventris*). Male nominate race is striking, mostly black, somewhat glossy above and sooty black below, with deep red or scarlet hood extending to uppermost breast and enclosing black loreal stripe that extends in thin ring around eye, and deep red to scarlet central upperbody (centre of mantle and back, and rump and uppertail-coverts) typically patchily mottled with black, especially on rump and uppertail-coverts (red of upperbody partly or wholly concealed when bird perched, but strikingly conspicuous in flight); upperswing and uppertail black-brown; undertail dark grey-brown; underwing-coverts dusky black, remiges pale grey-brown with glossy sheen and pale buff-grey bases (pale stripe across centre of underwing); iris brown to dark brown or grey-brown; bill black; legs blackish-grey to dark grey-brown. Female is smaller and duller than male, head and upperbody dull dark olive-brown or dark olive-grey, slightly paler rufous-brown on rump and uppertail-coverts, reduced dull red to red hood not extending to hindneck or breast, usually scattered small diffuse patches of red from centre of mantle to uppertail-coverts (some have reddish centre of mantle and back), uppertail blackish-brown, upperswing dark greyish-brown, median and greater wing-coverts with fine pale brown to buff margins, remiges with fine yellow-brown edges; underbody dirty buff-white to olive-buff, washed dark grey across upper breast, with diffuse dark olive-grey mottling or streaking on breast, flanks and belly petering out towards unmarked centre of belly and and somewhat warmer buff thighs, vent and undertail-coverts; undertail as male, underwing largely off-white with dark grey trailing edge and tip; bare parts much as male, but base of bill brownish, possibly gape sometimes yellowish. Juvenile is like female but slightly paler, with red confined to forehead, forecrown and chin and malar area (and sometimes as faint wash over ear-coverts), small scattered patches of red on upperbody, throat or breast (sometimes lacking), slightly broader and paler buff-brown fringes on upperswing-coverts and tertials, outer edges of remiges slightly brighter yellow-green, base of lower mandible paler (brownish-black or creamy grey), gape initially clearly swollen and yellow; immature male variable, at least some identifiable by contrasting mixture of adult-like scarlet-and-black male plumage and female-like plumage as well as some brownish retained juvenile plumage, some have head and upperparts much as adult but blackish underparts with pale greyish-olive wash over breast merging to more extensive pale greyish-olive mottling over lower underbody, also some brownish juvenile greater primary coverts with buff fringes (visible only in close view) and juvenile remiges (fringes and edges lost with wear), others have incomplete red hood with black of lores extending over eye to nape and hindneck and washing across red of malar area and anterior ear-coverts, and underparts as adult female, some possibly inseparable from adult male in field; immature female not properly known, probably less red on head than adult and less intense red on upperbody and underbody (but red wash extends onto belly), bill apparently at first paler basally (as immature male). Races differ in plumage and size, varying differentially with sex: *tenuis* is much smaller than nominate, especially in bill size (male mean bill length from 16.4 mm in N of range to 17.9 mm in S, nominate 18.8 mm), plumage very similar but immature (both sexes) brighter and tinged more olive, less brown, on upperbody and upperswing; *tucoptiae* is similar to previous, but bill even shorter (15.5 mm), adult male with red below confined to chin and throat (not extending to upper breast); *sanfordi* is similar in size to nominate, male with scarlet more extensive, reaching patchily to side of mantle, back and scapulars (but some with only scattered patches) and, below, continuing from throat over breast, upper belly and along flanks (patchily mottled black), rest of underbody black, sometimes with small scarlet patches or mottling, female like *sanctaecrucis* but largely dark brownish-olive above with red top of head, hindneck, lores, ear-coverts, most of chin to upper breast, faint reddish mottling or patches on mantle to rump (lacking distinct red) and red uppertail-coverts; underbody olive-buff, reddish mottling or wash on lower breast, grey mottling on side of breast and flanks; *sanctaecrucis* is larger than previous, male similar but with scarlet of upperbody more like that of nominate, female brownish-black to dark olive-brown above, slightly paler on head and neck, with strong red wash on forehead and weaker suffusion of dark red on rest of head and neck, scarlet scaling or mottling on mantle and back, wholly scarlet rump and uppertail-coverts, dull yellow-olive margins on wing and tail feathers, dark buff-brown or brown-olive underbody (paler than upperparts), darker and with dull red wash or mottling on breast; *pulcherrima* is smaller than nominate, male like previous (a few adult males have gape brownish or olive-brown, but not known if this occurs in other races), female with head and neck, middle of mantle and back, and rump and uppertail-coverts red, scapulars, side of back, and wing and tail dull black or blackish-brown, brownish fringes on wing-coverts and dull olive outer edges on remiges, underbody largely brownish-grey, anterior flanks blackish or blackish-brown, and breast, upper belly and rest of flanks faintly washed red; *lifuensis* is like nominate but smaller, male with red not extending to upper breast, and red and black sharply demarcated, female lacking red in plumage (other than faint wash on forehead and crown) and with upperparts generally darker olive-grey, chin and throat pale grey; *nigriventris* is like nominate but smaller, with much shorter bill (16–17 mm), male plumage similar, female differs from nominate in having top of head, neck and upperbody brownish-black, with scattered patches of scarlet (as nominate) or with reddish confined to lower back and rump. **VOICE.** Vocal, but not noisy, with variety of short, sharp syllables. Usual call a sharp high-pitched “tzwee” or “tzeer” (Vanuatu) or “zeet” or “tvee” (Samoa), uttered almost constantly during foraging, or sharp “chrrr” or “cheet”, rising in pitch and given singly or up to five times in succession (Rennell); “tzeer” also as threat or alarm; also a short, dry “tk” or “tch”; juvenile heard to utter wheezy descending “cheeet”. Song, usually from high perch, a repeated brief, melodious, tinkling or warbling “tzweety-tzweety-tweet-tweet-tweet”, more lively during breeding season; song described also as slurred whistles but with dawn song louder and consisting of clear whistled phrases, but rich disyllabic whistles described also as separate from song.

Habitat. Primarily forest, but occupies wide range of habitats on all islands on which recorded, occurring wherever flowering plants found, including primary and secondary forest, forest edge and mangroves; commonly in modified habitats, including plantations (especially of coconut palms), isolated trees, gardens and other urban and village habitats. In surveys in Samoa, recorded on Upolu more commonly in coastal fringe vegetation, in lowland forest to 30 m tall and dominated by tava (*Pometia pinnatifida*) and in foothill forest 20–30 m tall and dominated by mamalava (*Planchonella torricelliensis*), less commonly in tall or low montane forest (6–18 m or more tall) dominated by maotea mea (*Dysoxylum huntii*), and not recorded in exotic plantations, also more abundant in partly logged forest than in unmodified forest (often using gaps in canopy in former); on Tutuila more abundant in modified habitats than elsewhere (though still common in undisturbed forests), and in one detailed study most abundant in highly disturbed village habitat (variety of exotic flowers in plantations and gardens provides year-round source of nectar, though apparently competitive interactions with larger *Fouleaia carunculatus* can limit access to some of these plants); on Savai'i, numbers higher in upland cloudforest than lowland tava forest. In Santa Cruz Is, common on Vanikoro in gardens, plantations and secondary forest, occasionally in primary forest. Sea-level and coastal lowlands to mountains, in Solomons mainly along coast on Makira and Ugi, recorded to 455 m on Vanikoro, and recorded to 1250 m in Vanuatu; on Efate (Vanuatu) more common at higher altitudes; in Samoa at all altitudes but decreasing in abundance in montane forest; on Tutuila (American Samoa) recorded from lowlands to mountain tops but more common at higher altitudes (400–600 m), somewhat less common in lowlands and foothills (0–200 m), and lowest densities at intermediate altitudes.

Food and Feeding. Nectar, also pollen, possibly other plant material; also small arthropods, including insects and spiders (Araneae). A small snail (Gastropoda) was fed to a nestling in Samoa. Takes nectar from wide variety of sources, including ornamental hibiscus, ginger, bananas and Indian mulberry (*Morinda*) from gardens; on Tutuila, exotic flowers in plantations and gardens (such as coconut palms and ornamental plants e.g. *Hibiscus*, *Morinda* and *Carica*) provide year-round source of nectar, and native and introduced species of *Erythrina* provide large seasonal supplies of nectar when in flower. Forages at all levels, apparently mainly in middle and upper levels of forest, and said to prefer tall flowering trees. Constantly active, flitting through foliage and between flowers; perches on even finest twigs to reach flowers. Forages by probing and glean-ing; long bill and tongue enable it to reach deep into flowers. Also acrobatic, hanging or sally-hovering to reach flowers. Chases insects through foliage, and sallies from vegetation to catch them in flight; one seen entangled in spider web, and assumed to have been trying to obtain trapped insects. Usually singly or in twos (probably pairs), occasionally in family parties, but gathers in large numbers at sources of abundant food, particularly flowering trees and coconut palms; sometimes associates with other species, and in Solomon Is described as being in mixed-species flocks more often on Rennell (race *sanfordi*) than on San Cristobal or Three Sisters (*pulcherrima*). Ag-gressive towards conspecifics and other small nectarivorous birds, including *M. tristrami*, over which dominant at food, and spends much time in quarrelling and chasing; chases sometimes end in brief fights (lasting for a few seconds), birds jumping or flying at each other, grappling and even tumbling to ground together.

Breeding. In Vanuatu season Sept to Dec/Jan, with some evidence of breeding Jun; in Samoa thought to breed in all months (nestlings found in Jul and Sept, dependent young Jun and late Nov, male with brood patch mid-Mar); in Solomon Is dependent fledgling early Dec, and on Rennell independent juveniles and juveniles in post-juvenile moult common in first half Sept. Most nest-building by female, nest a small delicate open cup, usually of loosely woven grasses, fine grass fibres or fine roots and spider web, sometimes moss attached to exterior, usually suspended by rim from thin fork of branch or from vine, site varies from high in tree to almost on ground but thought to be often high (more than 3 m up), nearly always in dense foliage and well hidden; two nests in Samoa were built 2.5–3 m above ground, and another was 8 m up in crown of coconut palm. Clutch generally 2 eggs, rarely 3, but apparently 3–5 in Samoa and 4–5 in American Samoa; incubation said to be mostly by female, assisted by male, period 12–14 days; both sexes tend chicks, nestling period 12–14 days.

Movements. Resident, some local movement in search of blossom or other food sources. Locally, may be completely absent for long periods, and then numerous again when nectar abundant. Commonly flies between close islands, and occurs transiently on tiny islets; in Solomons, race *pulcherrima* vagrant on Santa Ana (off E San Cristobal).

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA, in Rennell and Bellona EBA, in Vanuatu and Temotu EBA, in New Caledonia EBA, and in Samoan Islands EBA. Widespread and generally common or abundant throughout most of range; not uncommon in Loyalty Is. Estimated population in American Samoa (Tutuila) 9940 individuals, at average density of 91/km² (0.91 birds/ha); earlier estimate of 118,000 birds considered unreliable. Often in urban and agricultural landscapes and common in disturbed habitats throughout much of range, and at some locations where studied this species is more numerous in disturbed sites than in undisturbed ones. Was previously caught and plucked for feather-money in the Santa Cruz Is and possibly elsewhere, but this practice appears to have died out.

Banks (1984), Beichle (2008), Beichle & Baumann (2003), Bellingham & Davis (1988), Bregulla (1992), Buckingham *et al.* (1995), Cain & Galbraith (1956), Clapp & Sibley (1966), Craig (2005), Dhondt (1976), Diamond (1970, 2002), Doughty *et al.* (1999), Dulson (2007a), Evans *et al.* (1992), Freifeld (1999), Freifeld *et al.* (2001), Hadley & Parker (1965), Hannecart & Létocart (1980), Koopman (1957), Kratter *et al.* (2006), Layard & Layard (1878, 1880), Mayr (1931a, 1932, 1937, 1940, 1945b), Mayr & Diamond (2001), Mayr & Hamlin (1931), McCarthy (2006), duPont (1976), Pratt *et al.* (1987), Schönwetter & Meise (1981), Tarburton (2001), Watling (1982a, 2001), Webb *et al.* (1999), Whitmee (1875).

103. Black-bellied Myzomela

Myzomela erythromelas

French: Myzomèle à ventre noir **Spanish:** Mielero Ventrinegro

German: Flammenkopf-Honigfresser

Other common names: Black-bellied/New Britain (Red-headed) Honeyeater, New Britain/Splendid Myzomela

Taxonomy. *Myzomela erythromelas* Salvadori, 1881, New Britain. May be part of a superspecies with *M. chermesina*, *M. chloroptera*, *M. wakoloensis*, *M. boiei*, *M. sanguinolenta*, *M. caledonica*, *M. rubratra* and *M. cardinalis*; limits of this superspecies, however, not certain and present species should perhaps be excluded; further study required. Monotypic.

Distribution. New Britain, in Bismarck Archipelago.

Descriptive notes. 9–10 cm; male 7–9 g, female 6.5–7.5 g, mean of 46 unsexed birds 8 g. Tiny short-tailed honeyeater. Male is striking, wholly black, except for scarlet hood marked with narrow black loreal stripe continuous with narrow black eyering; underwing sooty black, silvery grey panel across bases of remiges; iris dark brown; bill black; legs grey to blue-grey, soles yellow. Female is slightly

ings and gardens; in Whiteman Range recorded in lowland and high tropical rainforest. Lowlands and foothills, to c. 900 m. Replaced at higher altitudes by *M. cruentata*.

smaller than male, largely plain olive, a little paler below, with red mask covering forehead, forecrown, anterior ear-coverts, malar area and chin and throat, lores dusky; tail dark brown; bill blackish with paler basal third of lower mandible, gape said to be yellowish, rest of bare parts as for male. Juvenile undescribed; immature said to resemble adult of respective sex, but no further information. VOICE. Calls include rapid “tsi-tsi-tsi...”, fine, thin, squeaky notes, and a seesawing call, all three likened to calls of Black Sunbird (*Leptocoma sericea*).

Habitat. Primary forest, forest edge and secondary growth, and fairly common in clear-

Food and Feeding. Nectar, probably also small arthropods. Forages mainly in outer foliage of crowns of trees, but lower at forest edge and in secondary growth; seen to forage also in flowering vines. Usually in small parties in flowering trees, but sometimes in large congregations; in Whiteman Mts, large numbers foraging with other species in crowns of flowering trees in rainforest; at Mt Uali, seen to forage with *M. cineracea* and *M. cruentata*.

Breeding. Fledged juveniles seen in early Jul. Nest an open cup, one suspended in dense tendrils of vine. No other relevant information.

Movements. No information; probably resident, with local movements to exploit flowering of foodplants, this supported by obvious fluctuations in local numbers.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. Locally common to fairly common. Widespread and common in W New Britain, and abundant in Whiteman Mts.

Bibliography. PLATE 48

Family MELIPHAGIDAE (HONEYEATERS) SPECIES ACCOUNTS

104. Red-headed Myzomela

Myzomela erythrocephala

French: Myzomèle à tête rouge **German:** Rotkopf-Honigfresser **Spanish:** Miellero Cabecirrojo
Other common names: (Mangrove) Red-headed Honeyeater, Mangrove Red-headed Myzomela

Taxonomy. *Myzomela erythrocephala* Gould, 1840. King Sound, north Western Australia. Forms a superspecies, and sometimes treated as conspecific, with *M. dammermani* and *M. kuehni*; all three closely related to the *M. cardinalis* superspecies. Races intergrade in C & S Torres Strait. Two subspecies recognized.

Subspecies and Distribution.

M. e. infusca W. A. Forbes, 1879 – Aru Is, coastal S New Guinea (Triton Bay E to Domara, E of Cape Rodney) and islands of Torres Strait.

M. e. erythrocephala Gould, 1840 – islands of C & S Torres Strait, and from N Western Australia (near Broome, in S Kimberley Division) E along coast, including offshore islands and islets (such

as Melville I and Sir Edward Pellew Group, in Northern Territory), to N Queensland (Cape York Peninsula S on E coast to Princess Charlotte Bay).

Descriptive notes. 11–13 cm; male 7–11 g, female 6–9.4 g (nominate). Male nominate race has dark red hood marked with narrow black loreal stripe continuous with thin black ring around eye, sooty-brown upperparts, dark red on rump and uppertail-coverts (sometimes extending onto lower back), red of hood and rear upperbody often patchily mottled black; uppertail and upperwing blackish-brown, tertials and median and greater secondary coverts with narrow grey fringes, remiges with thin grey edges (diffuse pale panel on folded wing); sooty-brown band across upper breast grading into light brownish-grey below; undertail dark

grey, underwing dark grey with mostly white lining; iris dark brown; bill black or blackish-brown, sometimes brown or pink-brown basal half of lower mandible, gape black or yellowish; legs dark grey to brown or black, soles yellow. Female is smaller than male, has head, neck and upperbody grey-brown, merging to paler grey-brown on lower throat, and with obvious pink-red forehead, anterior ear-coverts, malar area, chin and upper throat and, sometimes, a few dark pink-red flecks on crown and uppertail-coverts; uppertail and upperwing dark brown, fringes and edges as for male although edges of remiges can be slightly paler (yellow); breast light grey-brown, grading slightly paler on lower underbody, and merging to off-white in centre of belly; bare parts as for male, gape yellowish. Juvenile is very like female, but rump and uppertail-coverts slightly paler and distinctly warmer brown than rest of upperbody, fringes of secondary coverts and tertials broader and light brown, pink-red on face sometimes much fainter (but usually conspicuous, as on female), base of lower mandible yellowish, yellow gape initially swollen, and iris and legs possibly paler; immature male not well known, like adult female but separable by patchy redder feathering on head and neck, and rump and uppertail-coverts, combined with dusky loral stripe and eyering, and some appear to have dark red partial hood. Race *infuscat*a differs from nominate in blacker upperbody and breastband, otherwise darker grey underparts, red of rump always extending to lower back, female darker above and more uniform and darker grey-brown below than nominate, with little pink-red on forehead. **VOICE.** Song a repetitive metallic jingling sound; contact call described as brisk and rather harsh “chiew-chiew-chiew”, which may be same as usual call described as buzzing and harsh “caseep” sounds. Other calls include shrill loud “cheep”, buzzing chirp, rather sharp and harsh chirrup when foraging; in New Guinea, also a harsh “zit”.

Habitat. Mangrove thickets or forests, especially extensive stands typically dominated by combinations of *Rhizophora*, *Bruguiera*, *Avicennia*, *Ceriops*, *Campostemon* or *Aegiceras*. In Australia, also often in vegetation on landward edge of mangroves or nearby along tidal creeks or samphire flats, including stands of paperbarks (*Melaleuca*) or casuarinas on littoral dunes; occasionally in open forest or swamp-woodland dominated by eucalypts and paperbarks (sometimes with thickets of *Pandanus*), patches of monsoon rainforest, rarely in semi-deciduous mixed woodland on coastal dunes and tall grassland and rarely in coconut plantations. Often in or around settlements and towns. Mainly at about sea-level, in coastal and subcoastal zones; in Australia, occasionally on near-coastal tablelands, to c. 800 m.

Food and Feeding. Primarily nectar; also small arthropods (mainly insects, some spiders). Forages mainly at flowers and in outer foliage in canopy of trees, especially flowering mangroves and mistletoes (Loranthaceae), less often in paperbarks or eucalypts up to 3 km from coast; of 291 observations of foraging in Darwin Harbour, 77% in mangroves and rest in other plants, such as vegetation fringing mangroves. Of observed feeding heights in Darwin, 4.4% at or below 1 m above ground, 16.8% at 1.1–2 m, 27.3% at 2.1–4 m, 32.4% at 4.1–8 m, and 19% above 8 m. Active when foraging, darting rapidly from flower to flower, and sallying for flying insects. In Darwin Harbour, 85% of foraging observations involved probing of flowers for nectar, the rest gleaning insects from foliage and twigs (14%), sally-striking in air (less than 1%) and sally-hovering (less than 1%). Usually singly or in twos (probably pairs), sometimes in small parties of up to four, and possibly more, individuals; in Australia, often associates loosely with other species such as *Lichmera indistincta*, fantails (*Rhipidura*) and others. Aggressive, and often chases or fights with conspecifics and *Lichmera indistincta*; males grapple in mid-air, often almost falling to ground before breaking away. In Darwin Harbour, defends feeding territories in flowering *Bruguiera exaristata* for much of dry season (May–Oct), but moves between sources of nectar during wet season (Nov–Apr); when food in short supply (Mar–May), establishes small feeding territories in cadjeput (*Melaleuca cajuputi*).

Breeding. No information for New Guinea. In Australia, breeding recorded Mar, Jun–Oct and possibly Nov, eggs recorded May–Oct; in Darwin Harbour, young fledged when *Ceriops australis* in flower. Nest a small cup made of pieces of bark, leaves, plant fibre, fine rootlets and sometimes seaweed, bound with spider web (which mainly near rim), usually lined with similar but finer material (one nest unlined), external diameter 5–5.8 cm, depth 3–4.3 cm, internal diameter 3.8–4.1 cm, depth 2.5–3.6 cm; suspended by rim from small horizontal fork of branch in foliage of mangroves, usually over water but up to 5 m from it; one in clump of mistletoe in mangroves, mean height above ground or water 1.5–5.4 m (mean 3 m), but in N Western Australia most nests 6–10 m above ground or water. Clutch 2 eggs, rarely 3; no information on duration of incubation and nestling periods; nestlings seen to be fed by female, and both adults seen with fledged young.

Movements. In Australia and at least some islands of Torres Strait generally considered resident, but numbers in an area can fluctuate, indicating at least local movements, possibly related to flowering of food trees. Around Darwin, in N Northern Territory, moves locally in wet season; occasionally occurs S of normal range in Queensland, but historical report from Moreton Bay (SE Queensland) probably involved misidentification. Also described as nomadic or to move locally, e.g. in S Torres Strait, and an irregular visitor to some sites. In New Guinea, in mangroves of Mimika R mouth, common at times but absent at other times.

Status and Conservation. Not globally threatened. Locally common to fairly common. No estimates of overall abundance; recorded at mean densities of 0.04–5.5 birds/ha.

105. Sumba Myzomela

Myzomela dammermani

French: Myzomèle de Sumba **German:** Sumbahonigfresser **Spanish:** Mielero de Sumba
Other common names: Sumba Honeyeater

Taxonomy. *Myzomela erythrocephala dammermani* Siebers, 1928, Sumba, Lesser Sundas. Forms a superspecies, and sometimes treated as conspecific, with *M. erythrocephala* and *M. kuehni*; all three closely related to the *M. cardinalis* superspecies. Monotypic.

Distribution. Sumba and Roti (off SW Timor), in Lesser Sundas.

Descriptive notes. 11 cm. Male is distinctive, with dark red head and neck forming hood, sharply demarcated from blackish mantle, back and scapulars, and with narrow clear-cut black loral stripe extending in thin ring around eye; rump and uppertail-coverts dark red; upperwing blackish, fine ashy-grey margins on coverts and remiges forming diffuse pale panel on folded wing (pale fringes on coverts become much reduced with wear, but pale panel on remiges remains distinct); uppertail blackish; below, dark red hood sharply demarcated from broad blackish band across breast and anterior flanks, this grading into paler grey-black on rest of underbody; undertail dark grey, underwing white with dark grey trailing edge and tip; iris dark brown; bill black; legs dark grey to blackish-brown. Female undescribed, but field observations suggest that sexes differ in much the same way as do those of *M. erythrocephala* (i.e. female grey-brown above, tail and wing darker, some areas of reddish colour on at least head, chin and throat, mostly light grey-brown below). Juvenile and immature undescribed. **VOICE.** Undescribed; considered quiet.

Habitat. Mainly primary forest, especially deciduous forest, and often seen at forest edge; recorded also in evergreen forest with *Acacia*. In study on Sumba, found to have preference for edges of primary forest with above-average proportion of deciduous trees. Claims that it occupies mangroves and adjacent vegetation apparently incorrect. Lowlands to 930 m or more.

Food and Feeding. No details of diet. Seen mainly in middle storey to canopy levels of forest; of 84 observations, 77.4% in canopy (more than 15 m above ground), the rest at middle levels (5–15 m). Seen singly, in twos (probably pairs) and in groups of up to seven individuals.

Breeding. No information.

Movements. Resident; probably at least some local movements to exploit flowering plants.

Status and Conservation. Not globally threatened. Restricted-range species: present in Sumba EBA. Total population on Sumba estimated at 129,600 individuals, based on density of 120 birds/km² in forest. Only recently recorded on Roti, where status not known.

Bibliography. Coates & Bishop (1997), Jepson (1993b), Johnstone & Jepson (1996), Jones, Banjaransari & Grimmett (1990), Jones, Linsley & Marsden (1995), Koopman (1957), Linsley *et al.* (1999), Mayr (1944a), Sibley & Monroe (1990), Trainor (2005b), White & Bruce (1986).

106. Crimson-hooded Myzomela

Myzomela kuehni

French: Myzomèle de Wetar **German:** Wetarhonigfresser **Spanish:** Mielero de la Wetar
Other common names: Wetar/Crimson-hooded/Banda Honeyeater, Banda/Kühn's/Wetar Myzomela

Taxonomy. *Myzomela kuehni* Rothschild, 1903, Wetar, Lesser Sundas.

Forms a superspecies, and sometimes treated as conspecific, with *M. erythrocephala* and *M. dammermani*; all three closely related to the *M. cardinalis* superspecies. Monotypic.

Distribution. Wetar, in E Lesser Sundas.

Descriptive notes. 11 cm. Male has head back to rear of ear-coverts dark red, forming bold hood sharply demarcated from grey of hindneck, mantle, back and scapulars, and with rather broad black loral stripe extending to narrow black band on forehead and thin ring around eye, as well as into malar area below eye (indistinct malar stripe resulting from black feather bases of otherwise red facial feathers); rump and uppertail-coverts dark red (as head); upperwing dark olive-brown, coverts and remiges with narrow pale fringes and edges (diffuse pale panel on folded wing), uppertail dark olive-brown; below, red hood extends down to breast, sharply

demarcated from whitish or pale yellowish-white underbody, undertail dark grey; bill black or blackish-brown; iris blackish-brown; legs blackish-grey. Female, juvenile and immature undescribed. **VOICE.** Calls include moderately high-pitched downslurred whistle, “tsiew”, repeated at rate of c. 1–1.5 notes per second; and short, thin, high-pitched insect-like “tsii-tsii”, syllables repeated every c. 6.5 seconds. **Habitat.** Lowland monsoon forest and gardens; recently observed in mosaic of coastal scrub, overgrown cultivation and tall secondary woodland.

Food and Feeding. No information on diet. Occurs from understorey to canopy; seen singly and in twos (probably pairs), sometimes in mixed-species foraging flocks.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Timor and Wetar EBA. Very poorly known. Apparently scarce. Although large areas of forest still remain on Wetar, some logging is now taking place; there have been plans for transmigration within Indonesia to the island, as it currently has only a small human population. Conservation measures proposed for the Endangered Wetar Ground-dove (*Gallicolumba hoedtii*), which include a proposed reserve of c. 450 km² (with full spectrum of habitats) in W Wetar, likely also to benefit present species.

Bibliography. Anon. (2007a), Butchart & Stattersfield (2004), Coates & Bishop (1997), Collar *et al.* (2001), Koopman (1957), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), White & Bruce (1986).

107. Mountain Myzomela

Myzomela adolphinae

French: Myzomèle montagnard **German:** Arfakhonigfresser **Spanish:** Mielero de Adolfinia

On following pages: 108. Scarlet-bibbed Myzomela (*Myzomela sclateri*); 109. Ebony Myzomela (*Myzomela pammelaena*); 110. Scarlet-naped Myzomela (*Myzomela lafargei*); 111. Black-headed Myzomela (*Myzomela melanocephala*); 112. Yellow-vented Myzomela (*Myzomela eichhorni*); 113. Malaita Myzomela (*Myzomela malaitae*); 114. Sooty Myzomela (*Myzomela tristrami*); 115. Orange-breasted Myzomela (*Myzomela jugularis*); 116. Red-rumped Myzomela (*Myzomela vulnerata*); 117. Red-collared Myzomela (*Myzomela rosenbergii*); 118. Green-backed Honeyeater (*Glycichaera fallax*).

Other common names: Mountain (Red-headed)/Red-headed Mountain Honeyeater, Mountain Red-headed Myzomela, Adolphina's/Elfin/Midget Myzomela

Taxonomy. *Myzomela adolphinae* Salvadori, 1876, Arfak Mountains, north-west New Guinea. Closely related to the *M. cardinalis* superspecies. Some reported variation between specimens from S & SE New Guinea and those from Huon Peninsula and Arfak Mts, with males of S & SE blacker on upperbody and upper breast but with lighter red head, and females also darker above and on breast; study needed. Monotypic.

Distribution. Mountains of W, N & E New Guinea (Vogelkop, C North Coastal Range, Central Highlands E from L Kapiago, Adelbert Mts, Huon Peninsula and SE).

Descriptive notes. 9–10 cm; unsexed mean 7.4 g, two females 7 g and 8 g. Tiny myzomela, and smallest honeyeater. Male is distinctive but somewhat variable, mostly dark grey to dusky black, merging to off-white on belly, flanks, vent and undertail-coverts, with red to bright red hood marked with blackish loreal stripe continuous with blackish ring around eye and short, diffuse and narrow dusky line or smudge behind eye; bright red rump and uppertail-coverts, dark grey uppertail; upperside dark brownish-grey, darker than mantle, back and scapulars (on darker individuals, wing blackish and concolorous with back), greater wing-

coverts finely margined paler brown, remiges with fine olive-brown outer edges (paler panel on folded wing); iris blackish brown to black; bill black, sometimes merging to yellowish base or basal toms of lower mandible, gape black or yellowish; legs dark greenish-grey or yellowish-grey. Female is largely olive-grey, merging to paler dirty white or off-white on belly and flanks to undertail-coverts, with diffuse reddish wash in malar area, lower ear-coverts, chin and upper throat (reddish face), diffuse pale eyering, yellowish-olive fringes on median and secondary coverts and pale yellowish outer edges on remiges (pale panel on folded wing); some may show faint reddish or rufous tone on forehead; gape pale yellow (never black). Juvenile and immature undescribed (nestlings have yellowish-horn bill, blackish-brown irides, brownish legs, yellowish feet). **VOICE.** Calls include high-pitched upslurred “sweeti”, descending wheezy “tzzew”, high-pitched “tsit”, harsh churring calls, and several short rapidly uttered notes. Song of 2 high-pitched notes, the first higher and often upslurred, second often trilled (“tyink”, often followed by somewhat musical, slightly downslurred and lower-pitched trill, appears also to describe song). Song in Varirata National Park said to be very different from those of populations elsewhere in E New Guinea.

Habitat. Montane and mid-montane primary forest, tall secondary growth and other modified habitats, such as settlements and towns, gardens, open areas and farmland, including groves of casuarinas or eucalypts in towns or agricultural areas; common also in *Castanopsis* oak woodland, and described as common in towns in Central Highlands; occasionally in eucalypt savanna in Varirata National Park. Mostly lower mountains between c. 1150 m and 2000 m, but down to c. 500 m and as high as 2225 m.

Food and Feeding. Nectar; small arthropods, apparently mainly insects, including small beetles (Coleoptera) and small homopteran bugs. Frequents canopy of forest, and usually seen well only in gardens and disturbed habitats, in flowering trees. Nectar obtained by probing flowers of canopy vegetation (including *Rhus taitensis*); insects gleaned from foliage. Active and vocal, but often inconspicuous. Usually seen singly, less often in small parties, when sometimes chase each other; readily associates with other species, including congeners such as *M. nigrita*, *M. eques* and *M. cruentata*, in flowering trees.

Breeding. Two nests with chicks in mid-Jul and late Oct (Wahgi Valley). One nest a neat, finely made cup woven into dead bracken frond that projected 10 cm in front of nest to make a verandah, described as having external roof and sides of trailing pale lichen loosely woven into bracken (appears to be unique within genus and rare in family, but frequency of such nest construction by this species not known); at this nest, chicks fed by both parents. No other information.

Movements. Little information. Possibly largely resident, with local movements to exploit flowering plants.

Status and Conservation. Not globally threatened. Generally fairly common to common, but patchily distributed; can be scarce or absent at sites. Common in disturbed sites and in towns and gardens.

Bibliography. Beehler (1978a, 1980b), Beehler *et al.* (1986), Bell (1984b), Brown & Hopkins (1996), Coates (1990), Coates & Peckover (2001), Diamond (1972a), Diamond *et al.* (1989), Eastwood (1989b), Finch (1978), Greenway (1935), Gyllenstolpe (1955a), Hartert (1930), Heron (1977a), Iova (1993), Koopman (1957), Mackay (1991), Mayr & Gilliard (1954), Mayr & Rand (1937), Rand & Gilliard (1967), Sims (1956), Tolhurst (1991), Wahlberg (1988), Watson *et al.* (1962).

108. Scarlet-bibbed Myzomela

Myzomela sclateri

French: Myzomèle de Sclater **German:** Palakuruhonigfresser **Spanish:** Mielero de Sclater
Other common names: Scarlet-bibbed/Red-bibbed/Scarlet-throated/Sclater's Honeyeater, Scarlet-throated/Sclater's Myzomela

Taxonomy. *Myzomela sclateri* W. A. Forbes, 1879, Palakūru, Credner Islands, off north-east New Britain. Relationships uncertain. Monotypic.

Distribution. Karkar I, off NE New Guinea, and small islands of Bismarck Archipelago, including Crown, Long, Tolokiwa, Tamuniai, Umboi, Unea (Bali), Witu Group, islets in Kimbe Bay and off N coast of New Britain. Talele, Watom and Credner Is (near Duke of York Is, including Nanuk and Palakuru Is).

Descriptive notes. 10.5–12 cm; male 10.5–12 g, female 10–11 g (Karkar), unsexed 10.5 g. Male has top and side of head and neck and upper mantle black-brown, merging to dark olive-brown on most of rest of upperparts, with paler olive-brown rump and uppertail-coverts; median and greater upperside-coverts with fine and diffuse olive fringes, remiges with fine olive outer edges (diffuse paler stripe or wash on folded wing); rectrices edged slightly paler brown; chin and throat bright red; upper breast dark olive-brown, merging into dirty olive-buff on lower breast and to dirty cream to off-white on lower underbody, indistinctly streaked or mottled brownish-grey on belly and anterior flanks; undertail dull greyish, underwing off-white with silvery grey-brown trailing edge and tip; iris blackish; bill black; legs slate-grey. Female is smaller than male, fairly drab, top and side of head and neck and most of upperparts brown to olive-brown above, with rufous-brown rump and uppertail-coverts, fine diffuse paler buff-brown fringes on upperside-coverts, fine yellowish

pair of short, hoarse buzzing notes, second one lower and trilled; and insistent “chip, chip, chip”. Vocalizations likened to those of white-eyes (Zosteropidae).

Habitat. Primary forest (including littoral forest), secondary growth and modified habitats, including coconut plantations; on Karkar also stunted montane shrubland and cool, damp, moss-laden forest at island summit. Sea-level to 1830 m; most islands occupied by this species are very small, low coral islets, other than the recently defaunated volcanic island of Long and neighbouring Tolokiwa and Crown (where occurs from sea-level to summit, at 600–1350 m); on Karkar mainly at 1000–1200 m, but visits lowlands at times.

Food and Feeding. Nectar, insects, fruit and parts of flowers. Forages from canopy to understorey; in forest below summits on Karkar, mainly above 3 m from ground, occasionally descending to understorey, but commonly seen foraging below 3 m in stunted summit shrubland. Gleans, probes and frequently sally-hovers. Noisy and active, making frequent flights of 5–10 m between feeding sites. Usually singly or in loose parties, and up to 15 seen foraging in single flowering tree; seen in flowering trees with other nectarivores.

Breeding. On Karkar, season appears protracted but probably started by May–Jun; nest with young in mid-Aug on Witu. Nest a thin-walled cup, occasionally with spider web attached to exterior, apparently suspended and well concealed, usually in low vegetation (e.g. 2 m above ground in clump of canegrass), but up to 10 m above ground in coconut palm. No information on clutch size and incubation and nestling periods; both parents feed nestlings.

Movements. Resident; on Karkar, may undertake seasonal altitudinal movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. Generally common or abundant. Status on Umboi uncertain; at least occasionally occurs, with early reports pre-1955 and more recent records (1994). Possible occurrence on Biem (Bam) I, in Schouten Is (NW New Guinea), seems unlikely.

Bibliography. Beehler *et al.* (1986), Chemnick & Melli (1993), Coates (1990), Coates & Peckover (2001), Diamond (1970a), Diamond & LeCroy (1979), Diamond *et al.* (1989), Eastwood & Gregory (1995), Finch (1981c), Koopman (1957), Mayr (1955), Mayr & Diamond (2001), Rand & Gilliard (1967), Schipper *et al.* (2001), Schönwetter & Meise (1981), Stattersfield *et al.* (1998).

109. Ebony Myzomela

Myzomela pammelaena

French: Myzomèle ébène **German:** Ebenholz-Honigfresser **Spanish:** Mielero Ébano
Other common names: Ebony/Admiralty/Bismarck (Black/Island)/Black Honeyeater, Admiralty/Bismarck (Black)/Black/Islet Myzomela

Taxonomy. *Myzomela pammelaena* P. L. Sclater, 1877, Nares Harbour, Admiralty Islands, Bismarck Archipelago.

Forms a superspecies with *M. lafargei*, *M. melanocephala*, *M. eichhorni*, *M. malaitae* and *M. tristrami*, and formerly suggested that all may be conspecific; this group possibly closely related to the *M. cardinalis* superspecies. Present species formerly treated as conspecific with *M. nigrita*. Population of Wuvulu I currently placed in race *ernstmayri*, but may belong to a different race. Racial identity of recently observed individuals on Timor I (in Kimbe Bay), off NC New Britain, uncertain (possibly *nigerrima*). Racial differences slight. Five subspecies recognized.

Subspecies and Distribution.

M. p. ernstmayri Meise, 1929 – small islands W of Admiralty Is, including Wuvulu, Manu, Ninigo, Anchorites (Kaniet) and Hermit.

M. p. pammelaena P. L. Sclater, 1877 – Admiralty Is (E Manus, probably established; Rambutyo, Lou, Nauna, and other small islands, including Mandrin, Baluan, Sivisa, Los Reyes, San Miguel, Ponam, Hauwei and Tong).

M. p. hades Meise, 1929 – St Matthias Group (Mussau, Eloaua, Emirau and Tench), NW of New Hanover.

M. p. ramsayi Finsch, 1886 – Tingwon I and small islands off New Hanover (e.g. Tigak) and off N New Ireland, in Bismarck Archipelago.

M. p. nigerrima Salomonsen, 1966 – islands of Long, Crown and Tolokiwa and associated small islets (including Midi, Hein and islets of Siassi Group), between NE New Guinea and Umboi.

Descriptive notes. 11–12.7 cm; male average 17 g, female average 14.6 g, male 12–14 g (*hades*, *ramsayi*), male 13.2–20 g (other races). Male nominate race is entirely glossy black, except for blackish-grey axillaries and underwing-coverts; iris brown to blackish; bill black; legs dark grey to black. Female is very like male but slightly smaller and a little duller. Juvenile is wholly dusky brown, slightly browner below; immature probably black with patches of brownish-grey admixed. Races differ in size and underwing colour: *ernstmayri* has black coloration very similar to that of nominate, perhaps with less gloss, adult male

slightly larger than in nominate, with bill stronger and, on average, longer; *nigerrima* is similar to previous but still larger (male wing 77–79 mm, *ernstmayri* 75–77 mm), also deeper black (with darker greyish-black bases of feathers), male glossier; *hades* is smaller than nominate, with whitish axillaries and underwing-coverts; *ramsayi* resembles last (male wing for the two combined 65–69 mm). **VOICE.** Main call of race *nigerrima* a relatively loud (for *Myzomela*), hoarse, unmusical scolding; vocalizations of *hades* vary, including frequent “sweet, sweet, sweet...”, with notes repeated up to six times, chipping notes like those of a sunbird (Nectariniidae), and a song “shwee, shwee...suit” or “swit”. Nominat race gives harsh “ssht, ssht” during chases.

Habitat. Virtually all available vegetated habitats: primary forest, secondary growth, shrubland, coconut plantations, gardens and around human habitation. On Long I in more open coastal habitats, including fruit gardens, and commonly in crowns of coconut palms. On Manus, occurs on coast and up to 3 km inland, in tall isolated trees. Recorded from sea-level to summits on Long I (maximum elevation 1300 m), Tolokiwa I (c. 1300 m) and Crown I (c. 570 m).

Food and Feeding. Nectar and insects. Forages from understorey and shrub layer to canopy, by cleaning and probing; commonly in flowering shrubs (including hibiscus) and trees. On Manus, seen to forage on leafless branches of a flowering tree, hovering often and fluttering vertically downwards. Conspicuous, often chasing each other. Seen singly, in twos (probably pairs) and in small parties (e.g. of up to six individuals), occasionally in larger gatherings of up to 30 or more in flowering trees; on Manus, in Jun–Jul, three tight cohesive flocks of 3–5 birds seen. In Ninigo Is, thought to defend food resources, and vigorously attacked intruders.

Breeding. Single nest (with nestlings) reported, on 29th Apr: a small cup of fine plant fibre, suspended from horizontal fork 2–4 m above ground in outer foliage of small tree, nest concealed by foliage from above. No other information.

Movements. Probably largely resident, with local movements. Probably now established on Manus, where formerly recorded as a vagrant or occasional visitor from nearby islets, some of which are as little as c. 1 km away.

Status and Conservation. Not globally threatened. Restricted-range species: present in Admiralty Islands EBA, in St Matthias Islands EBA, and in New Britain and New Ireland EBA. Generally common to abundant; considered common on Mussau, Long, Tolokiwa, Crown and Tong; abundant in Ninigo Is; common on Tigak I (off New Hanover). On Manus, recent records of small flocks, and comments by local people that species is found uncommonly on the island; increasing area of degraded vegetation on Manus may have allowed this “supertramp” species to establish a breeding population there. Usually not present on large islands of New Hanover and New Ireland, twice sighted in W New Hanover.

(1975), Buckingham *et al.* (1995), Chemnick & Melli (1993), Coates (1990), Coates & Peckover (2001), Coates & Swainson (1978), Diamond (1976), Diamond *et al.* (1989), Eastwood (1996b), Eastwood & Gregory (1995), Gregory (1995c, 2007), Koopman (1957), Leavesley & Leavesley (2000a, 2000b), Mayr (1932), Mayr & Diamond (2001), Salomonsen (1966a), Schipper *et al.* (2001), Silva (1975), Stattersfield *et al.* (1998), Tolhurst (1993).

110. Scarlet-naped Myzomela

Myzomela lafargei

French: Myzomèle à nuque rouge

Spanish: Mielero Nuquirrojo

German: Scharlachnackten-Honigfresser

Other common names: (Small) Bougainville/Scarlet-naped/Red-naped/Red-crowned Honeyeater, (Small) Bougainville/Red-naped/Red-capped Myzomela

Taxonomy. *Myzomela lafargei* Pucheran, 1853, Santa Isabel, Solomon Islands.

Forms a superspecies with *M. pammelaena*, *M. melanocephala*, *M. eichhorni*, *M. malaitae* and *M. tristrami*, and formerly suggested that all may be conspecific; this group possibly closely related to the *M. cardinalis* superspecies. Monotypic.

Distribution. Buka, Bougainville, Shortland Is, Choiseul (and Arnavaon I) and Santa Isabel (and Malakobi and Megapode), in N Solomon Is.

underbody; underwing largely white; iris brown to greyish-brown or dark grey-brown; bill black; legs olive-grey to yellowish-grey, soles yellow. Female is smaller than male, has head and neck greenish-grey to olive-grey, grading to greyish-green or dusky olive on upperbody, with diffuse darker mottling or streaking on crown, reddish-brown tinge in malar area and lower ear-coverts (and possibly chin); wing olive-grey, pale edges of remiges as on male, underbody below throat yellowish-grey to yellowish-olive. Juvenile is like female, but bill duller, grey-black, apparently swollen gape yellow to orange-yellow, and juvenile male probably has some red on forehead and forecrown; immature male not fully described, like adult female but darker above, olive-brown to dark olive-grey, with varying red to scarlet streak in centre of forehead and forecrown (or these areas wholly red), reddish-brown malar area, lower ear-coverts and possibly chin and throat (which described also as bright red), darker below, bill at least sometimes remains duller grey-black, legs grey-brown; immature female very poorly known, possibly indistinguishable in field from adult. **Voice.** Variety of brief calls: sweet, high-pitched “tsip-tsip” like that of a sunbird (Nectariniidae); sharp whistled “chip” or “chitt”; loud dry “chtt” or “chtt, chtt”; reedy cheeps. Rapid twittering song.

Habitat. Lowland, middle-altitude and montane primary forest, including cloudforest, forest edge, also tall secondary forest in lowlands and mountains, lowland swamp-forest, mangroves and other coastal habitats, and modified habitats, including farm clearings in forest, coconut plantations, gardens and villages. Sea-level to above 2000 m. Tends not to co-occur with Olive-backed Sunbird (*Cinnyris jugularis*), although the two are sometimes found in same general area (e.g. around Mabiri and at Burunotui, on W coast of Buka); present species, however, is a forest-dweller that ranges to high altitudes, whereas this sunbird is typically in open country and below 800 m.

Food and Feeding. Nectar and insects. Observed mainly in crowns of trees, including flowering coconut palms in gardens, but forages at all levels, from understorey to canopy. Gleans and probes; also sally-hovers to feed at flowers. Active. Usually seen singly, in twos (possibly pairs) or in small flocks; often in larger numbers in flowering trees, often with lorikeets (of genera *Charmosyna* and *Trichoglossus*). Occasionally forages with Olive-backed Sunbirds in flowering plants at forest edges or at edges of water.

Breeding. Female carrying food in mid-Jan; most birds at c.1500 m in Jul–Aug were in breeding condition, whereas those in lowlands at same time were not. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA. Fairly common on Bougainville, uncommon on Choiseul and rare on Santa Isabel.

Presumably still present on Arnavaon I (E of Choiseul) and on Malakobi and Megapode (off N coast of Santa Isabel), but no recent information.

Bibliography. Diamond (1975), Doughty *et al.* (1999), Dutson (2007a), Hadden (1981, 2004), Kaestner (1987), Koopman (1957), Kratter, Steadman, Smith & Filardi (2001), Kratter, Steadman, Smith, Filardi & Webb (2001), Mayr (1932, 1945b), Mayr & Diamond (2001), Schodde (1977), Smith & Filardi (2007), Stattersfield *et al.* (1998), Virtue (1947), Webb (1992).

111. Black-headed Myzomela

Myzomela melanocephala

French: Myzomèle à tête noire **German:** Savohonigfresser **Spanish:** Mielero Cabecinegro
Other common names: Black-headed/Black-cowled/Guadalcanal Honeyeater, Guadalcanal/Islet Myzomela

Taxonomy. *Cinnyris melanocephalus* E. P. Ramsay, 1879, Guadalcanal, Solomon Islands.

Forms a superspecies with *M. pammelaena*, *M. lafargei*, *M. eichhorni*, *M. malaitae* and *M. tristrami*, and formerly suggested that all may be conspecific; this group possibly closely related to the *M. cardinalis* superspecies. Monotypic.

Distribution. Guadalcanal, Savo and Ngella, in EC Solomon Is.

Descriptive notes. 12–13 cm; male 11–14 g, female 10–12.5 g. Male is predominantly rich olive above and on side of neck and breast, with partial glossy black mask covering forehead and crown (merging into olive of hindneck), lores, ear-coverts, malar area and chin and throat; uppertail and upperwing dark olive-brown, median and greater wing-coverts with fine diffuse olive fringes, remiges with fine olive outer edges (olive panel or stripe on folded wing); breast rich olive, continuous with side of neck, merging to slightly dusky, dark greyish-olive lower underbody, which varyingly mottled darker, blackish, especially on

belly and flanks; undertail grey-brown, underwing off-white with silvery grey-brown trailing edge and tip; iris dark brown; bill black; legs slate-grey to greenish-grey or dark brown, soles yellowish. Female is smaller and slightly duller than male, possibly with slightly smaller mask and paler lower underbody (confirmation needed); gape sometimes yellow. Juvenile not fully described, but differs from adult in duller and smaller mask, duller upperparts, greyish-buff belly, also bill dull yellow basally (wholly in one bird), gape bright yellow; immatures apparently like adult but duller, with strong cinnamon or rufous tinge in olive plumage, especially on rump and uppertail-coverts, on lower underbody and on margins of upperwing-coverts. **Voice.** Rather quiet. Short, sharp high-pitched “chiip-chiip” or loud, rather musical piping “teep...teep...”, sometimes with variants (“tleep” or “ti-eeep”); other calls include rapid “ti ti ti ti...” by agitated bird in flight, an unmusical “weh weh weh”, and repeated thin and very metallic “seseses chiu...” interspersed with “sesesh” and “cheh” phrases. Some calls somewhat like those of *M. eichhorni* but softer.

Habitat. Primary forest, forest edge, tall secondary forest, and modified habitats including gardens. Sea-level to at least 1550 m; said also to occur at all altitudes on Guadalcanal, and possibly more abundant at high altitude.

Food and Feeding. Few data on diet; stomachs found to contain insects (mostly small, but one large soft-bodied insect 12.5 mm long). Seen to peck ineffectively at fruit and to investigate myrmecophilous epiphytes. Mainly in canopy, also lower levels at forest edges and in disturbed areas. Forages mainly at flowers, including coconut flowers. Agile and active, often hanging upside-down to reach flowers and jumping from twig to twig, while flicking wings; occasionally sally-hovers, and once seen to sally from (and return to) a perch, presumably after flying insects. Usually seen singly.

Breeding. Newly fledged and still downy young observed mid-Nov. No other information.

Movements. Probably resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA. Very poorly known or, at least, poorly described in literature. Considered common within small range, but described also as rather uncommon on Guadalcanal.

Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Doughty *et al.* (1999), Dutson (2007a), Koopman (1957), Mayr (1945b), Mayr & Diamond (2001), Ogilvie-Grant (1888), Rothschild & Hartert (1901), Smith & Filardi (2007), Stattersfield *et al.* (1998), Stevens & Tedder (1973).

112. Yellow-vented Myzomela

Myzomela eichhorni

French: Myzomèle à ventre jaune

Spanish: Mielero de Eichhorn

German: Rotbürzel-Honigfresser

Other common names: Yellow-vented/Eichhorn’s/Kulambang(a)r/New Georgia/Central Solomons Honeyeater, Crimson-rumped/Eichhorn’s/Kulambang(a)r Myzomela

Taxonomy. *Myzomela eichhorni* Rothschild and E. J. O. Hartert, 1901, Kolombangara, Solomon Islands.

Forms a superspecies with *M. pammelaena*, *M. lafargei*, *M. melanocephala*, *M. malaitae* and *M. tristrami*, and formerly suggested that all may be conspecific; this group possibly closely related to the *M. cardinalis* superspecies. Three subspecies recognized.

Subspecies and Distribution.

M. e. atrata E. J. O. Hartert, 1908 – Vella Lavella and Bagga, in WC Solomon Is.

M. e. ganongae Mayr, 1932 – Ranongga (S of Vella Lavella).

M. e. eichhorni Rothschild & E. J. O. Hartert, 1901 – Ghizo, Kolombangara, Wana Wana, Kohinggo, New Georgia, Vangunu, Rendova and Tetepare, in WC Solomon Is.

Descriptive notes. 12–13 cm. Male nominate race is predominantly dark olive-grey above, slightly darker on head and hindneck and darker blackish-olive on wing and tail, with scarlet rump and uppertail-coverts, and prominent yellowish-olive margins on wing-coverts and remiges (pale panel on folded wing); chin and throat scarlet, underbody paler yellow-olive; iris brown to dark brown; bill black; legs horn-coloured (silvery) grey to black, with yellow soles. Female is like male but smaller, with upperparts slightly paler, more olive, scarlet on rump and uppertail-coverts replaced with cinnamon-olive or rufous-olive, scarlet throat patch duller and smaller, underbody paler, buff-olive; outermost tail feathers have pale tips. Juvenile is very dull brown-grey, with no olive-green tinge above or below, and with dark reddish-grey spot in middle of chin and throat; immature

plumages not well known, male dark brownish-olive above, darker on top of head, with reddish wash on forehead, cinnamon to rufous rump and uppertail-coverts, olive-cinnamon wing-covert margins, olive edges of remiges and rectrices, dark greyish-olive chin and throat with scarlet feathers in centre, underbody pale cinnamon-olive, tinged buffy olive in centre of belly, largely whitish underwing; immature female apparently like adult but with cinnamon wash throughout (particularly on rump). Races quite similar, differing mainly in overall darkness of plumage; *atrata* is darker than nominate, dull blackish with olive tinge

above, dull blackish-olive below, some males with traces of red on nape; *ganongae* is intermediate between previous and nominate. **Voice.** Frequently gives loud, sharp, high-pitched "tzeep", "bzeet" or "tit-it-tit"; also a sharp "zeeet-zeeet" during aerial chasing. Rapid high-pitched trilling song, like that of Rufous Fantail (*Rhipidura rufifrons*) but faster and not descending scale.

Habitat. Primary forest and tall secondary forest, and seen also at forest edge bordering village gardens, and in gardens and coconut plantations and groves. On Kolombangara common in all habitats with trees or shrubs, and most abundant in high moss forest; near town of Kena, recorded most often in coastal coconut groves, less often in secondary growth and least often in primary forest. Sea-level to 1500 m or above; more numerous at higher altitudes on Kolombangara.

Food and Feeding. Mainly nectar, but also regularly visits ant-plants (myrmecophilous epiphytes) at high altitudes. Said to prefer forest canopy, at least 10 m above ground, but forage also in understorey vegetation. Most reports of small parties, e.g. of up to five in flowering trees, and a family party of adults and two juveniles; up to three seen in mixed-species feeding flocks.

Breeding. Free-flying juveniles in late Aug. No other information.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA. Not well known. Considered common to fairly common.

Bibliography. Blaber (1990), Buckingham *et al.* (1995), Doughty *et al.* (1999), Dutton (2007a), Koopman (1957), Mayr (1932, 1945b), Mayr & Diamond (2001), Sibley (1951), Smith & Filardi (2007), Stattersfield *et al.* (1998).

113. Malaita Myzomela

Myzomela malaitae

French: Myzomèle de Malaita **German:** Malaitahonigfresser **Spanish:** Mielero de la Malaita
Other common names: Red-bellied/Malaita Honeyeater, Red-bellied/Red-vested Myzomela

Taxonomy. *Myzomela cardinalis malaitae* Mayr, 1931, Malaita, Solomon Islands.

Forms a superspecies with *M. pammelaena*, *M. lafargei*, *M. melanocephala*, *M. eichhorni* and *M. tristrami*, and formerly suggested that all may be conspecific; this group possibly closely related to the *M. cardinalis* superspecies, and has been suggested that present species may belong with latter group. Monotypic.

Distribution. Malaita, in E Solomon Is.

Descriptive notes. 12–13 cm; male 13–17 g, female 10.5–12.5 g. Male is predominantly dull black, merging into olive-black on vent and undertail-coverts, and with prominent scarlet rump and uppertail-coverts, and broad scarlet streak on centre of chin and throat grading into scarlet breast and flanks (belly black); uperwing-coverts and remiges finely edged olive (diffuse panel on folded wing), rectrices finely edged olive; underwing-coverts grey; iris brown; bill black; legs bluish-grey. Female is smaller than male, pale greyish-brown to olive-brown above, darker head and neck dull blackish-brown, reddish forehead and fore-

crown and chin-throat, and rufous-red rump and uppertail-coverts; uperwing-coverts finely edged buff-brown, remiges edged olive (paler panel on folded wing), rectrices finely edged olive; underbody buff-olive to yellowish-olive, slightly paler in centre of belly and vent; bare parts as male. Immature male is like adult female, but with more red, having forehead and forecrown redder (sometimes with dark brown mottling), chin and throat red, and rump and uppertail-coverts dull rufous-cinnamon to rufous-red; immature female probably as adult. **Voice.** High-pitched "see-see", usually given in flight.

Habitat. Mainly primary forest; uses secondary growth in some places, but absent from secondary forest in many areas; found also in scrub and gardens. Sea-level to mountain summits; more common in hills and mountains.

Food and Feeding. Seen to forage, presumably for arthropods, with mixed-species flocks, and at ant-plant (myrmecophilous epiphyte) flowers. No other information.

Breeding. No information.

Movements. No information; probably sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Solomon Group EBA. Scarce or uncommon. Large areas of lowland and hill forest throughout Malaita are being degraded by logging and by clearance for gardens for increasing human population. Much of this meliphagid's population, however, occurs above the altitudes currently threatened by logging or clearance.

Bibliography. Anon. (2007a), Bulchar & Stattersfield (2004), Doughty *et al.* (1999), Dutton (2007a), Gibbs (1996b), Koopman (1957), Mayr (1931b, 1945b), Mayr & Diamond (2001), Smith & Filardi (2007), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

114. Sooty Myzomela

Myzomela tristrami

French: Myzomèle de Tristram **German:** Tristramhonigfresser **Spanish:** Mielero de Tristram
Other common names: Sooty/Melanic/Santa Ana/Tristram's Honeyeater, Santa Ana/Tristram's Myzomela

Taxonomy. *Myzomela Tristrami* E. P. Ramsay, 1881, San Cristobal, Solomon Islands.

Forms a superspecies with *M. pammelaena*, *M. lafargei*, *M. melanocephala*, *M. eichhorni* and *M. malaitae*, and previously suggested that all might be conspecific; this group may be closely related to the *M. cardinalis* superspecies. Present species formerly considered conspecific with *M. nigrita*. Reported as hybridizing with *M. cardinalis* on San Cristobal. Monotypic.

Distribution. San Cristobal, Santa Ana and Santa Catalina, probably also Ugi, in E Solomon Is.

Descriptive notes. 11–12 cm; male 12.5–16.5 g, female 11.5–14 g. Male is wholly black with faint violet-blue sheen, except for duller and brownish-tinged remiges, slightly paler greyish-black to dull blackish axillaries and underwing-coverts (varyingly mottled off-white), and pale silvery panel across bases of otherwise dark brown remiges on underwing; iris black-brown; bill black; legs slate-grey to black, sometimes with bluish tinge. Females is smaller than male, and possibly slightly duller and with slightly paler legs (but doubtfully distinguishable in field). Juvenile is duller than adult, sooty black above and greyish-olive below

(or blackish with pale grey mottling or smudging below), bill dark yellow to orange-yellow with grey-black distal third, gape bright yellow, and legs paler; immature like adult, but slightly duller black above, olive-grey below with black mottling on breast and belly, and bill dark yellow with black tip. **Voice.** Rather quiet. Vocalizations include soft twitters and whispered chirps, "tz, witecher-witecher-witecher" and "churr, churr, churr-chirr, chi chi chi, churr, churr"; song, heard at dawn (twice), a short nasal whistle followed by fast and then slow twitter, "oowae-oo, chit-it-it-it..chit..chit..chit". Also frequent short sharp contact calls; wheezy upslurred "tweest" when excited.

Habitat. Primary and secondary forest, and modified habitats, including coconut plantations and gardens; occupies all vegetated habitats throughout San Cristobal. Lowlands and mountains, from sea-level to c. 900 m; more common on coast and at middle altitudes than in foothills or at 700–900 m.

Food and Feeding. Mainly nectar, also small insects; once seen to carry a small fruit, which was dropped and caught again in mid-air. Forages mainly in canopy of forest or crowns of tall trees, including coconut palms and large garden trees; also in tall secondary growth and substages where forest disturbed. Searches on outside of crowns of trees or shrubs. Seldom singly; often in small parties of c. 6 individuals (often with more subadults than adults), but also congregates in larger numbers (up to ten, possibly more) in flowering trees, where sometimes forages with *Meliarchus sclateri* and parties of Duchess Lorikeet (*Charmosyna margarethae*); tends to move away from larger *Meliarchus sclateri*. Occasionally joins mixed-species flocks (up to three individuals of present species per flock).

Breeding. Nest with eggs on 5th Sept: nest like that of sunbird (Nectariniidae) but broader and less deep, suspended 10 m above ground from branch of understorey tree. No other information.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species: present in Solomon Group EBA. Poorly known. Considered generally common to abundant; on San Cristobal, very numerous on coast and moderately common inland. Status on Ugi not certain; considered vagrant or occasional visitor, but possible that a resident population exists; study needed.

Bibliography. Buckingham *et al.* (1995), Diamond (1976, 2002), Doughty *et al.* (1999), Dutton (2001), Koopman (1957), Mayr (1932), Mayr & Diamond (2001), McCarthy (2006), Rothschild & Hartert (1908), Stattersfield *et al.* (1998).

115. Orange-breasted Myzomela

Myzomela jugularis

French: Myzomèle des Fidji **German:** Orangebrust-Honigfresser **Spanish:** Mielero Pechinaranja
Other common names: Orange-breasted Honeyeater, Sulphur-breasted Myzomela

Taxonomy. *Myzomela jugularis* Peale, 1848, Vanua Levu, Fiji.

Related to the *M. lafargei* superspecies. Monotypic.

Distribution. Fiji: all main islands and most smaller islands and islets from Yasawa Group S to Kadavu and E to Lau Group.

Descriptive notes. 9–11 cm; male 8–10 g, female 8–9 g. Tiny, short-tailed honeyeater with long, rather slender and decurved bill. Male has head and neck mostly black, with crimson rear crown to nape, dull crimson chin and upper throat usually narrowly bordered below by black or blackish band across lower throat, and yellow to orange-yellow wash on throat and upper breast (latter often mottled blackish, particularly in mid-line); upperbody black, scarlet mottling on lower back, rump and uppertail-coverts (or these tracts mostly scarlet with varying black mottling or scaling); uppertail black-brown, varying small white tip

most obvious on outer rectrices (becomes much reduced or lost with wear); uperwing black, broad white tips on median secondary coverts and fine off-white to buff tips or terminal fringes on greater coverts (two ill-defined broken wingbars, much reduced or lost with wear), fine yellowish-olive outer edges on remiges (yellowish panel on folded wing); yellowish breast merging into dirty white to pale yellow on rest of underbody, diffusely and inconspicuously mottled blackish on sides and belly; undertail black-brown with broad white tip (reduced or lost with wear), underwing white with olive-brown trailing edge and tip; iris black, brownish-black or dark grey-brown; bill and gape black; legs grey-black to blue-black, soles yellow. Female is similar to male but smaller, duller and less strongly marked, with black of head, neck and upperbody sooty black, sometimes paler on top of head and on face, red of upperparts duller, and red on hindcap, rump and uppertail-coverts much reduced in extent or lacking; uperwing patterned as in male but ground colour duller, sooty black to olive-black; chin and upper throat duller red, yellow wash on lower throat and breast weaker and duller and more strongly mottled blackish. Juvenile lacks red in plumage, similar to female but duller still, with faint olive tinge on lower back to uppertail-coverts, single white wingbar (median coverts), and chin to breast dirty olive-grey (with no red), merging to pale greyish-white below; immature male like adult female but darker above, dark olive-brown to blackish-olive, usually no or at most a few red feather tips on nape and rump to uppertail-coverts, much as adult female below (chin and upper throat duller than adult male); immature female similar to immature male, but red confined to chin and duller, lower throat duller (less yellowish),

never any reddish tips on nape or rump. VOICE. Frequently a strident “chit-chit” or “sweet-sweet”, especially from flocks, which can produce almost continuous high-pitched trilling. Song a phrase of 2–4 syllables “tee-ter”, “tzwee-tzwee”, “tsu-tzwee-tzwee” or “tsee-ooop-tee-dee”, uttered monotonously (sometimes aggravatingly) by male from songpost, usually high in tree, for an hour or more; monotonous “tziit” punctuated by higher “tchee” possibly also describes song. Flight call “tee-too, tee-too-tee...”; another call a high-pitched “tee-tee-tee-tee”. Fledged young beg with squeaky “see see”.

Habitat. All habitats, including primary and secondary lowland, hill and montane forest, coastal forest and mangroves; common in disturbed habitats, including roadsides, clearings in forest, plantations and agricultural land, towns, villages and gardens, and scattered trees in open country. On Lakeba, in Lau Group, most abundant in disturbed habitats, especially coastal coconut plantation and mixed and pure pine woodland; decline in relative abundance with maturity of forest, being less numerous in secondary forest on carbonate rock and scarcest in mid-successional to late-successional forest on limestone. In Lomaiviti Group, recorded in all habitats on Gau and Makogai, including mature secondary scrub-forest with virtually no herb layer (grazed by goats) and coconut plantations on Makogai, and dense mature rainforest on Gau. On Viti Levu recorded from 30 m to 1310 m; from near sea-level to 970 m on Taveuni.

Food and Feeding. Mainly nectar; also takes many arthropods, including spiders (Araneae) and insects. Forages at all heights, from low herbs and shrubs up to canopy of tall forest, occasionally on ground; active, even appearing frenetic at times, darting between flowering plants and hopping among small branches and foliage. Takes nectar from wide variety of flowers (e.g. hibiscus, and introduced weed *Stachytarpheta*), by probing while perched, while hanging or while sally-hovering; occasionally pierces flower bases with bill. Gleans insects and spiders from on and around flowers and small branches; on Lakeba, common in nectar-poor habitats of pine woodland and suggested as largely insectivorous in these habitats. Normally seen singly, in twos (probably pairs) or in small groups; can gather in large numbers (30 or more) in flowering trees, when spend much time in chasing. Displaced by larger honeyeaters and by Collared Lory (*Phigys solitarius*).

Breeding. Recorded in all months except Mar–Apr; possibly double-brooded. Nest a fragile and loosely built cup made of grasses and fine rootlets, suspended between vertical stems among dense foliage of shrub, vine or small tree, usually below 4 m. Clutch 2 eggs; no information on incubation and nestling periods; young fed by both parents; family parties of adults and single young observed.

Movements. Mostly sedentary; in dry areas of W Viti Levu undertakes local movements, sometimes in small flocks, and can be absent for months before reappearing.

Status and Conservation. Not globally threatened. Restricted-range species: present in Fiji EBA. Common to abundant, e.g. common on Makogai and Gau, in Lomaiviti Group. Often found in modified habitats. Old reports from Samoa unsubstantiated.

Bibliography. Beckon (1993), Blackburn (1971), Brown & Child (1975), Clunie (1984), Gorman (1975), Holyoak (1979), Koopman (1957), Langham (1989), Mayr (1932, 1945b), McCarthy (2006), Morgan & Morgan (1965), Pernetta & Watling (1978), duPont (1976), Pratt *et al.* (1987), Schönwetter & Meise (1981), Steadman & Franklin (2000), Tarburton (1992), Watling (1982a, 1982b, 1985, 2001).

116. Red-rumped Myzomela

Myzomela vulnerata

French: Myzomèle de Timor **German:** Dreifarben-Honigfresser **Spanish:** Mielero Culiriojo
Other common names: Black-breasted/Sunda/Timor Myzomela, Red-rumped/Black-breasted/Black-chested/Sunda/Timor Honeyeater

Taxonomy. *Nectarinia* (*Myzomela*) *vulnerata* S. Müller, 1843, Timor, east Lesser Sundas. Relationships uncertain; suggested as being close to *M. erythrocephala*, or possibly close to the *M. cardinalis* superspecies. Monotypic.

Distribution. Timor, in E Lesser Sundas.

Descriptive notes. 10.5 cm. Distinctive and striking: has broad black mask across lores, malar area, narrowly over eye and side of neck and joining black breastband and black of mantle, back and scapulars, isolating scarlet cap and scarlet patch on chin and throat; rump and uppertail-coverts scarlet, uppertail blackish; upperwing mostly blackish, narrow greyish margins on coverts and remiges forming diffuse pale panel on folded wing (pale fringes on coverts much reduced with wear, but pale panel on remiges remains distinct); underbody below breastband white to greyish-white; iris blackish; bill and gape black; legs black. Sexes

similar in plumage, male apparently larger. Juvenile and immature undescribed. VOICE. Weak, high-pitched insect-like note, repeated monotonously at intervals of c. 1 second, “sit-sit-sit-...”; rapidly repeated series of similarly toned disyllabic notes, “tipa-tipa-tia-tipa-...”, second syllable lower than first.

Habitat. Mainly secondary monsoon forest and scrub, also in primary forest. Recorded from sea-level up to 1300 m.

Food and Feeding. Mainly nectar, also insects. Forages mostly from middle storey to canopy; at flowers in trees (including *Eucalyptus*) and other plants. Very active, but inconspicuous and infrequently observed; singly or in twos (probably pairs).

Breeding. Female carrying food in early Dec, and immatures or juveniles seen on three dates through May; extrapolated months of laying Mar–Apr and Nov. No other information.

Movements. Probably sedentary, with possibility of local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Timor and Wetar EBA. Generally moderately common, and locally very common.

Bibliography. Coates & Bishop (1997), Hellmayr (1914), Koopman (1957), Mayr (1944a), Noske (2003), Noske & Saleh (1994, 1996, 1997), Trainor, Coates *et al.* (2007), Trainor, Santana *et al.* (2008).

117. Red-collared Myzomela

Myzomela rosenbergii

French: Myzomèle de Rosenberg **German:** Rosenberghonigfresser **Spanish:** Mielero de Rosenberg
Other common names: Red-collared/Black-and-red/Red-caped/(Von) Rosenberg’s Honeyeater, Black-and-red/Red-caped/Rosenberg’s Myzomela

Taxonomy. *Myzomela rosenbergii* Schlegel, 1871, Arfak Mountains, north-west New Guinea. Relationships within genus uncertain; may be close to the *M. cardinalis* superspecies or to the *M. lafargei* superspecies. Proposed race *wahgiensis* (Weiga, S slope Wahgi Divide, in Western Highlands) considered inseparable from nominate. Two subspecies recognized.

Subspecies and Distribution.

M. r. rosenbergii Schlegel, 1871 – high mountains of New Guinea from Vogelkop E, including Bewani Mts (C North Coastal Ranges), Adelbert Mts and mountains of Huon Peninsula, to Owen Stanley Range.

M. r. longirostris Mayr & Rand, 1935 – mountains of Goodenough I, in D’Entrecasteaux Archipelago.

Descriptive notes. 10–12.5 cm; male 9.3–12.7 g, female 9–10.7 g (nominate), three males 12.4–15.6 g, three females 7.5–8.5 g (*longirostris*). Male nominate race is striking, glossy jet-black except for broad, brilliant scarlet collar covering all of hindneck, side of neck, throat and upper breast, continuous with scarlet mantle, back, rump and uppertail-coverts; scarlet of underbody has varying scattered black patches or mottling, and sometimes posterior uppertail-coverts wholly black; underwing sooty black with silvery grey-brown remiges; iris brown to blackish-brown; bill black; legs very dark grey to blackish-brown

or black, soles yellow. Female is smaller than male, plumage very different, black-brown above, grading to blackish-brown on lores, malar area and chin and upper throat, diffuse and faint rufous-brown mottling on forehead and crown merging to more pronounced mottling or streaking on hindneck to back and scapulars, with scarlet-red lower rump and most uppertail-coverts, posterior uppertail-coverts and tail usually dark olive-brown to black-brown (sometimes lower back wholly rufous-brown and posterior tail-coverts tinged rufous-brown); median and greater upwerving-coverts with rufous-brown tips (two wingbars, fairly weak across median coverts and appearing broken on greater), remiges with fine, slightly paler dark olive outer edges (palest and most pronounced on tertials); extent of pale tips appears to vary (possibly with wear), wing sometimes appears fairly uniformly blackish-brown, relieved only by pale tips of tertials; lower throat and upper breast red, forming crescent-shaped patch, on some extending to centre of lower breast, rest of underbody rufous-brown, variably mottled blackish to dark brown throughout, underwing white with silvery grey-brown trailing edge and tip; legs possibly slightly paler, light brown to brown or grey-black, rest of bare parts as male. Juvenile is poorly known, fairly uniformly dark brown to chestnut-brown above and slightly paler below, with red wash on breast, blackish remiges, buff-olive tips on median and greater coverts and tertials (broader than on adult female), gape yellow and swollen; immature male possibly varies, like adult female but darker, with diffuse rufous-brown mottling on nape, behind eye and on upper side of neck merging into red (mottled rufous-brown and black) from hindneck to anterior uppertail-coverts and continuous with brilliant red lower side of neck, lower throat and breast, sooty-black scapulars and posterior tail-coverts with faint rufous-brown tinge, worn brownish upwerving-coverts (probably retained from juvenile plumage) with rufous-brown tips, or worn rufous-brown “rosethorns” at tips, faintly paler brown fringes on tertials and outer edges of remaining remiges, underbody below breast black and variably mottled rufous-brown (some may be more like adult female); immature female poorly known, like adult but smaller patch of red on throat to breast, little or no red on underbody, largely rufous-brown forehead and crown streaked blackish-brown, less distinctly dark face, large rufous-brown rosethorns at tips of median and greater coverts, may also have dark postocular stripe. Race *longirostris* is larger and with much longer bill than nominate, male plumage much as nominate but red deeper and darker, female differs from nominate in having head and upperparts olive-brown, with red on nape, hindneck, mantle and rump to uppertail-coverts, olive-grey below, yellow tinge on chin and throat, red breast patch. VOICE. Often noisy. Vocalizations include high-pitched, upslurred and rather drawn-out “tuweeist” or shorter “tswi” or “tsi”, a high “ts-ts”, and harsh “chh” in flight. Song a breathless, high-pitched sibilant trill or rapid repetition of 2 notes on different pitches, which may be same as rushed, sibilant whistled “swi-swi swit-swi...” from canopy.

Habitat. Lower montane to high mountain primary forest, including cloudforest, moss forest, oak (*Castanopsis*) forest and dense riverine forest, and in forest edge and secondary forest; recorded also in alpine shrubland and *Pandanus* scrub; occasionally in gardens with flowering shrubs. In Snow Mts one seen well above tree-line at c. 3350 m in scattered shrubs growing on talus slope; at Dokfuma Meadow (Star Mts) recorded in subalpine herbfield with dense mat of ferns, small stands of tree-ferns and shrubs, and bordered by open *Dacrydium* woodland and some stands of mossy upper montane forest in sheltered areas. On Mt Albert Edward (SE New Guinea) common in dense *Dodonea* regrowth. On Goodenough I common in montane oak forest. The only New Guinea member of genus occurring above 2000 m; mainly between 1200 m and 3700 m, occasionally foraging down to 600 m; recorded to 3950 m in Snow Mts. On Goodenough I, common at 1000 m and above.

Food and Feeding. Primarily nectar; also small arthropods, occasionally small fruits. Nectar taken from wide range of flowering plants, including trees (e.g. *Albizia*, *Terminalia*, *Syzygium*, *Xanthomyrtus* and flowering rhododendron), epiphytes and vines and shrubs (including *Dimorphanthera*). Arthropods mainly insects, including beetles (Coleoptera) and Hymenoptera. Gleans from foliage and probes flowers. One hopped about in dense foliage of forest tree, pausing only briefly to search, until it reached a flower; it then hung beneath this and probed with bill. Active, aggressive and conspicuous. Often congregates in flowering trees, usually up to about twelve individuals but at times in larger numbers, e.g. 25–30 (mostly males); associates with other honeyeaters, and other bird species, in flowering trees. Also seen singly or in twos (possibly pairs).

Breeding. Nestlings recorded in late Jul and late Sept, fledglings mid-Jul and juveniles early Sept; “breeding birds” in Aug (one) and Oct–Dec. One nest a bulky cup made of rootlets and lined with finer rootlets, c. 3 m above ground in vertical fork of shrub. At one nest, young fed only by female. No other information.

Movements. Largely resident, but variation in local numbers to exploit flowering trees indicate at least local movement or dispersal; at Crater Mt, seen only during times of maximum flower availability.

Status and Conservation. Not globally threatened. Common to abundant; abundant in Albert Range at 1400–1600 m; considered common on Goodenough I. Males seen far more often than females (e.g. at one site, ratio estimated at 20+:1), suggesting either biased sex ratio in population or sexual differences in behaviour and conspicuousness or in ecology; on Mt Karimui (apparent sex ratio male-biased 7:1), some data indicate that males and females forage differentially in flowering trees, where most birds are sighted, and that sexes appear also to exhibit some altitudinal segregation. Skins of males are used as ornaments by Papuans in SE New Guinea, with head of skin placed through a hole in the ear-lobe.

Genus *GLYCICHAERA* Salvadori, 1878

118. Green-backed Honeyeater

Glycichaera fallax

French: M  liphage trompeur **German:** Gr  nmantel-Honigfresser **Spanish:** Mielero Dorsiverde
Other common names: Green-backed Straightbill, Grey-headed/Puff-backed Honeyeater; White-eyed Honeyeater (*fallax*); Pale-eyed Honeyeater (*poliocephala*)

Taxonomy. *Glycichaera fallax* Salvadori, 1878. Hall Sound, south-east New Guinea. Sometimes placed in genus *Timeliopsis*. Birds of this species on Salawati of unknown racial identity, provisionally included in *pallida*. Four subspecies recognized.
Subspecies and Distribution.
G. f. pallida Stresemann & Paludan, 1932 – West Papuan Is (Waigeo, Batanta, Salawati).
G. f. poliocephala Salvadori, 1878 – Misool I (West Papuan Is), Aru Is and lowland NW New Guinea E to head of Geelvink Bay (lower Menoo R) and Onin Peninsula (Kapaur).
G. f. fallax Salvadori, 1878 – Yapen I (Geelvink Bay) and lowland New Guinea E of Geelvink Bay and Onin Peninsula to Milne Bay.
G. f. claudi (Mathews, 1914) – NE Queensland (E Cape York Peninsula S as far as Princess Charlotte Bay), in NE Australia.

Descriptive notes. 11–12.5 cm; male 7.5–18 g and female 8–12 g (New Guinea), two males 10.5–11.5 g and female 9.5 g (*claudi*). Small, nondescript honeyeater with almost straight, moderately long and pointed bill. Nominate race has head and neck greyish olive-brown, slightly paler on lores, cheek and ear-coverts, narrow, pale yellow eyering; pale yellowish chin and throat with olive mottling; upperbody dark olive, yellow tinge on rump and uppertail-coverts; upperwing olive-brown, fine pale olive edges and tips on coverts and remiges; uppertail dark olive-brown with fine and diffuse olive edges; underbody dull yellowish, undertail brownish

grey, underwing yellowish with brownish-grey remiges; iris light blue-grey; bill grey-black on upper mandible, paler horn-coloured on lower, gape pinkish-buff; legs blue-grey to dull grey. Sexes alike in plumage, male slightly larger than female. Juvenile is very like adult but duller, with slightly paler face, paler and inconspicuous eyering; pale yellow fleshy gape, and brown iris. Race *pallida* is like nominate, but greyer, contrasting with back, and underparts paler; *poliocephala* has bill intermediate

between nominate and *claudi*, and further differs in much greyer upperparts, ashy-grey head and neck, grey tinge in olive upperparts, grey mottling on chin and throat, and pale yellow underbody; *claudi* has slightly longer and less curved bill and slightly longer wing and tail than others, also very pale yellowish chin and throat, and brighter pale greenish-yellow underparts with stronger yellow tone. **Voice.** In New Guinea, usual call described as repeated high-pitched “chick”, or as repetitive “whit whit”, notes spaced at intervals of c. 1 second; also an infrequent dry “chit”. In Australia, contact call a pleasant busy twittering, sometimes with slight upward inflection, given mainly in flight or after alighting; also soft single peep (audible only at close range) during foraging; rapidly repeated loud single “twit” during chasing, developing to longer “twee-twee-twit-twit” for a while, also given more slowly in response to presence of observer. In New Guinea, considered quiet and easily overlooked. **Habitat.** Primary and secondary tropical rainforest and rainforest edge, in Australia including gallery forest, semi-deciduous vine thicket, semi-deciduous mesophyll vine forest, and edges of rainforest bordering clearings and roads, and in New Guinea monsoon forest. Recorded also in swamp-forest, riparian scrub and, rarely, in mangroves in New Guinea. In Australia, occasionally at edges of eucalypt forest bordering rainforest. In examination of vegetation succession (from gardens to forest) resulting from slash-and-burn agriculture in New Guinea, found in late regrowth and undisturbed plots; in New Guinea often considered common in forest clearings and secondary growth. Lowlands; in New Guinea in lowlands and hills, mainly to 850 m, exceptionally to 1200 m, becoming less common with altitude. **Food and Feeding.** Primarily insectivorous; also takes small fruits (including of *Poikilospermum*), and seen to forage among eucalypt flowers, taking either nectar or insects. In Australia, forages usually in canopy, particularly upper canopy, to 20 m above ground; less often in small trees and shrubs at 2–6 m, rarely to within 1 m of ground. Foraging height in New Guinea less clear: said to forage often in substages and less often in forest canopy, but also, conversely, said to forage mainly in canopy; study needed. Searches mainly among foliage, also on outer branches and twigs, and among vines. Active, rapidly hopping and running along branches, flitting from tree to tree, sometimes hanging sideways or upside-down. Obtains insects from foliage typically by gleaning; also by sally-hovering at foliage (including undersides of leaves) or small branches, or by sally-striking in air. Usually singly, in twos or in threes; sometimes in small parties of 5–10 individuals during dry season, when regularly chase one another in short quick flights through and below canopy; birds usually stay within 1–5 m of each other, though can appear to be foraging individually at times. In Australia, often associates with Rufous Fantail (*Rhipidura rufifrons*), sometimes with Fairy Gerygone (*Gerygone palpebrosa*) and Lemon-bellied Flyrobin (*Microeca flavigaster*); in New Guinea, occasionally in mixed flocks of insectivores. **Breeding.** Very poorly known. In New Guinea, nesting observed in Aug and Dec, juveniles in Jul and Oct, and birds in breeding condition Jul, Oct and Dec; probably breeds in dry season in NE Australia (dependent fledgling Aug, and another Jun). Fledgling fed by both adults. Nests possibly parasitized by bronze-cuckoos (*Chrysococcyx*), as adult feeding cuckoo chick in New Guinea. No other information. **Movements.** Apparently resident, probably with some local movements. **Status and Conservation.** Not globally threatened. Locally common in New Guinea, but generally considered uncommon there. In Australia, race *claudi* fairly common but occupying only a small area; most records at Iron Range, but a specimen from McIlwraith Range; doubtful reports from near Weipa. **Bibliography.** Bailey (1992), Barrett *et al.* (2003), Beehler (1978a), Beehler, Pratt & Zimmerman (1986), Beehler, Sengo *et al.* (1995), Bell (1970c, 1982a, 1982b, 1982d, 1984b), Beruldsen (1979), Blakers *et al.* (1984), Bowman *et al.* (1990), Coates (1990), Finch (1980b, 1983), Forshaw & Muller (1978), Gannon (1962), Garnett & Crowley (2000), Geeves & Horton (1990), Gilliard & LeCroy (1967a, 1968), Greenway (1966), Gregory (1995b), Hartert (1930), Higgins *et al.* (2001), Holland (1972), Hoogerwerf (1971), Johnson & Hooper (1973), Keast (1968a), Longmore (1991b), MacGillivray (1915, 1918), Mack & Wright (1996), Mayr & Rand (1937), McAllan (1990), Ogilvie-Grant (1915), Pavey (1991, 1994), Rand (1942a, 1942b), Ripley (1964), Schodde & Mason (1999), Sch  nwetter & Meise (1981), de Silva Garza (1993), Terborgh & Diamond (1970).

Genus *PTILOPRORA* De Vis, 1894

119. Leaden Honeyeater

Ptiloprora plumbea

French: Méléphage gris-de-plomb **German:** Bleikehl-Honigfresser **Spanish:** Mielero Plomizo
Other common names: Leaden Streaked Honeyeater

Taxonomy. *Ptilotis plumbea* Salvadori, 1894, Moroka, south-east New Guinea. Two subspecies recognized.

Subspecies and Distribution.

P. p. granti Mayr, 1931 – patchily in Central Ranges of New Guinea (Nassau Mts E to Hindenburg Mts).
P. p. plumbea (Salvadori, 1894) – patchily in mountains of SE New Guinea, including Herzog Mts.

Descriptive notes. 14–15 cm; two males 13.5 g and 14 g, one female 12.5 g (nominate), one male 16.5 g (*granti*). Nominat race has head, neck and upperbody leaden grey, fine blackish-brown streaking on top of head, hindneck and side of neck, merging to dense fine pale grey to off-white speckling on side of head and chin and throat, and to broader and more diffuse blackish-brown streaking on mantle, back and scapulars (sometimes appearing as mottling); upperwing and uppertail grey-brown, browner than upperparts, wing-coverts and remiges with fine olive to olive-grey outer edges and tips (boldest on tertials and secondaries and basal edges of central primaries); underbody almost uniformly leaden grey, with fine and sparse white speckling across breast and olive-brown wash on belly; undertail brownish, underwing pale buff-grey with dark brownish-grey trailing edge and tip; iris typically light grey to silvery grey, in some (possibly immature) brown; bill black to grey-black; legs pale slate-blue or blue-grey. Sexes alike in plumage, male larger than female. Juvenile and immature apparently undescribed. Race *granti* is like nominate but slightly darker, slate-grey, with darker streaking on upperparts, and longer wing. Voice. Calls include whistled and somewhat breathy “wshee wshee wshee...”; and weak “teu teu” or “tswee” notes repeated about every 3 seconds.

Habitat. Mid-montane primary forest, forest edge and secondary growth; recorded also in gardens in Ok Tedi area. From 1000 m to 2100 m, possibly to 2400 m.

Food and Feeding. Arthropods and nectar from flowers. Forages from canopy level almost to ground, frequently in lower and middle stages (3–15 m above ground). Arthropods gleaned from foliage, twigs and petioles; nectar taken from flowers, including understorey flowers, e.g. ginger (Zingiberaceae). Not shy, but inconspicuous; active, continually flitting about when foraging in openings in forest. Usually seen singly, and often adopts posture with tail cocked; often flicks tail upwards.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Papuan Mountains EBA. Generally rare, and absent from much of Central and Eastern Highlands; can be fairly common to common locally, e.g. common in forest interior at Suria (Central Province, in SE New Guinea).

Bibliography. Beehler (1978a, 1978c, 1988), Beehler *et al.* (1986), Coates (1990), Coates & Peckover (2001), Diamond (1969), Eastwood & Gregory (1995), Gilliard (1950b), Gilliard & LeCroy (1961), Gregory (1995b), Mayr & Rand (1937), Murray (1988b), Ogilvie-Grant (1915), Rand & Gilliard (1967), Stattersfield *et al.* (1998).

120. Olive-streaked Honeyeater

Ptiloprora meekiana

French: Méléphage de Meek **German:** Meekhonigfresser **Spanish:** Mielero de Meek
Other common names: Yellowish(-streaked)/Meek’s (Streaked) Honeyeater

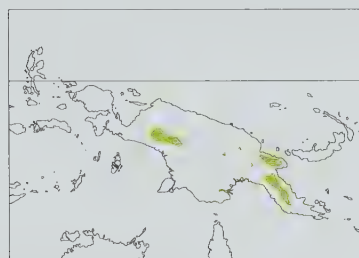

Taxonomy. *Ptilotis meekiana* Rothschild & E. J. O. Hartert, 1907, Upper Aroa River, south-east New Guinea.

In E New Guinea, isolated records at Tari Gap (Southern Highlands), Trauna Gap, near Baiyer River Sanctuary (Central Highlands), and Mt Michael (Eastern Highlands) involve birds of unknown racial identity; may represent an undescribed race (but specimen from Mt Michael intermediate between *occidentalis* and nominate). Two subspecies recognized.

Subspecies and Distribution.

P. m. occidentalis Rand, 1940 – upper slopes of E Nassau Mts and W Oranje Mts, in W New Guinea.
P. m. meekiana (Rothschild & E. J. O. Hartert, 1907) – Saruwaged Mts (Huon Peninsula), Herzog Mts and mountains of SE New Guinea (including upper Mambare R and Mt Tafa-Efogi area).

Descriptive notes. 16–17 cm; one male 18.5 g (nominate), two females 20–21 g (*occidentalis*). Nominat race has top and side of head and neck and upperbody yellowish-olive with bold blackish-olive streaking, streaks fine on top of head and hindneck, broader elsewhere, most prominent on mantle and back (aligning to give boldly striped appearance to upperparts); streaking on side of head fairly dense, giving diffusely masked appearance in which pale eye prominent; upperwing and uppertail blackish-brown to dark brown, darker than upperparts, narrow yellowish-olive edges on upperwing-coverts, remiges and rectrices; pale yellowish-olive below, with paler yellowish chin and throat and yellowish belly, strong dusky olive streaking throughout, strongest on throat; yellowish tuft at side of breast below angle of wing; undertail dusky brown, underwing pale yellowish with dark trailing edge and tip; iris light grey to greenish-grey; bill black, grey lower mandible and cutting edges, gape olive; legs blue-grey. Sexes alike in plumage, male larger than female. Juvenile and immature apparently undescribed. Race *occidentalis* is on average larger but with apparently shorter bill than nominate, also brighter all over, greenish (less grey-toned) above, with brighter rump and wing and tail edgings,

brighter throat with darker dusky streaking, and brighter yellowish underbody. Voice. Call note an indistinct “cht” or “chip”, frequently repeated.

Habitat. Mid-montane to montane forests and secondary growth. Recorded at 2200–2800 m in Snow Mts (race *occidentalis*); at 2440 m at Mt Michael; and from c. 1300 m to 2300 m, mainly 1500–2100 m, in SE (nominate).

Food and Feeding. Mainly arthropods, including medium-sized insects; also nectar from flowering trees. Forages usually in middle and upper levels of forest, and often in flowering trees; in Snow Mts, usually seen when gleaning through crowns of substage trees. Difficult to observe. Usually singly or in pairs; often in mixed-species feeding flocks in Snow Mts.

Breeding. Breeding female in Dec. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Adelbert and Huon Ranges EBA and in Central Papuan Mountains EBA. Poorly known. Considered generally uncommon to rare; locally common, e.g. on N slopes of Snow Mts.

Bibliography. Beehler (1978a), Beehler *et al.* (1986), Bishop (1987), Coates (1990), Coates & Peckover (2001), Diamond (1969, 1972a), Greenway (1935), Mayr & Rand (1937), Rand (1940a, 1942b), Rand & Gilliard (1967), Ripley (1964), Stattersfield *et al.* (1998).

121. Rufous-sided Honeyeater

Ptiloprora erythropleura

French: Méléphage à flancs roux **German:** Rotflanken-Honigfresser **Spanish:** Mielero Flanquirro
Other common names: Rufous-sided Streaked Honeyeater, Red-sided (Streaked) Honeyeater

Taxonomy. *Ptilotis erythropleura* Salvadori, 1876, Arfak Mountains, north-west New Guinea.

Formerly considered conspecific with *P. mayri*, *P. guisei* and *P. perstriata*, but the four differ in size, plumage (crown colour, dorsal coloration, colour of wing-covert edgings, distinctness of ventral spotting, flank colour) and iris colour. Present species is sympatric (and with broad altitudinal overlap) with *P. perstriata* over distance of at least 400 km in W New Guinea. Birds from Wissel Lakes area (between Weyland Mts and Snow Mts) described as race *incerta*, but validity uncertain, and thought possibly a hybrid between race *dammermani* and *P. perstriata* (of nominate race); further study needed. In NW (Bomberai Peninsula), female specimen in Kumawa Mts like race *dammermani* in size and iris colour, but with pale yellowish wash below; birds almost certainly of this species seen commonly in Fakfak Mts also had somewhat yellowish underbody, and thought by later researchers to differ from nominate race in larger size, distinct streaking below and lack of rufous in plumage (also, tuft at side of breast yellowish, and at least some had pale iris); both populations provisionally included with present species, but study required in order to determine whether they represent one or two undescribed races, or even new species. Two subspecies currently recognized.

Subspecies and Distribution.

P. e. erythropleura (Salvadori, 1876) – mountains of Vogelkop and Bomberai Peninsula, in NW New Guinea.

P. e. dammermani Stresemann & Paludan, 1934 – Weyland Mts E to Nassau Range and Oranje Mts, in W New Guinea.

Descriptive notes. 17 cm; male 21–25 g and female 18.5–20.5 g (nominate), one female from Kumawa Mts 21 g. Nominat race has head and neck leaden grey, fine and dense pale greyish speckling or scaling on forehead and lores and in diffuse suborbital crescent, fine pale dull olive edges on top of head and hindneck (faintly scaled or streaked effect); upperparts dusky to blackish-brown with fine and obscure dull olive-grey streaking or scaling, olive-brown wash on rump and uppertail-coverts; upperwing-coverts varying edged rufous to very pale olive, pale olive edges on remiges; underbody pale leaden grey, fine off-white to pale grey feather edges on breast and centre of belly (faintly scaled or streaked effect), chestnut-brown flanks; iris red, brownish-red or red-brown; bill black, sometimes blackish-grey; legs blue-grey to grey-blue or slate-grey. Sexes alike in plumage, male larger than female. Juvenile and immature not properly known, but plumage generally washed olive or creamy yellow to greenish-yellow, especially below. Race *dammermani* is like nominate but darker grey below, with darker brown flanks, iris apparently dull pale green, also wing slightly longer but tail possibly shorter (few data for latter). Voice. Song consists of plaintive whistled “chwee” notes given at rate of 2 per second. In Kumawa Mts and Fakfak Mts, consisted of high plaintive slurs repeated at intervals of 3–6 seconds (similar to song of *P. guisei*, *P. mayri* and *P. perstriata*); at least in Kumawa Mts, repeated element often 2–3 separate notes at different pitches, first one usually staccato.

Habitat. Mid-montane and montane forest and secondary growth. Recorded at 1300–2800 m; heard commonly above 1200 m in Fakfak Mts.

Food and Feeding. Diet includes arthropods (mainly insects), nectar and fruit (including berries). Forages mainly in middle and upper levels of vegetation, but extends to understorey; gleans and probes. Active, confiding, quick-moving and usually conspicuous; seen in twos (probably pairs) and in small groups (possibly family parties).

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in West Papuan Highlands EBA and in Central Papuan Mountains EBA. Not well known. Considered generally uncommon, but said to be quite common at higher altitudes in Arfak Mts; uncommon in Kumawa Mts.

122. Mayr's Honeyeater

Ptiloprora mayri

French: Méléphage de Mayr **German:** Mayrhonigfresser **Spanish:** Mielero de Mayr
Other common names: Mayr's Streaked Honeyeater

Taxonomy. *Ptiloprora guisei mayri* E. J. O. Hartert, 1930, Cyclops Mountains, north New Guinea. Formerly considered conspecific with *P. erythropleura*, *P. guisei* and *P. perstriata*, but the four differ in size, plumage (crown colour, dorsal coloration, colour of wing-covert edgings, distinctness of ventral spotting, flank colour) and iris colour. May form a superspecies with *P. guisei*, and often treated as conspecific with that species alone, but comparative studies indicate that the two are better considered separate species. Two subspecies recognized.

Subspecies and Distribution.

P. m. mayri E. J. O. Hartert, 1930 – Foja Mts and Cyclops Mts, in N New Guinea.

P. m. acrophila Diamond, 1969 – summit of Mt Menawa (Bewani Mts), in N New Guinea.

Descriptive notes. 19.5 cm; male 30–37.5 g and female 24–29 g (nominate), male 29.3–36.3 g and female 25.5–29.2 g (*acrophila*). Nominate race has top and side of head and neck and upperbody black-brown to dusky black, irregular pale grey streaking on top of head (grey edges of feathers; crown can appear pale with dark spotting), merging to pale rufous-brown mottling on lower hindneck and side of neck and to heavy pale rufous-brown mottling on mantle, back and scapulars, and more diffuse and weaker mottling on rest of upperbody; upperwing and upperpart blackish-brown, wing-coverts with pale grey outer edges, primaries with pale grey to olive-

grey outer edges; mostly light grey below, diffusely mottled dusky on chin and throat, distinctly streaked dusky grey on breast and belly, merging to dusky grey with rufous tinge and streaked with pale rufous-brown on sides of breast and belly and on flanks; vent and undertail-coverts as belly, but washed rufous-brown or yellowish and only faintly streaked; undertail brownish-grey; iris green or greyish-green; bill black; legs bluish-grey. Sexes alike in plumage, male larger than female. Juvenile is washed olive or greenish-yellow below. Race *acrophila* differs from nominate in having pale feather on forehead and crown slightly darker grey, merging to dull olive on nape and hindneck, rufous-brown edges on upperbody darker, duller and tinged olive, wing-covert edges varying light rufous-olive (not pale grey), and streaking below paler and greyer and less contrasting. **Voice.** Plaintive whistles. Song described as high plaintive slur repeated monotonously once every 3 seconds, but varying, e.g. a rising disyllable, descending disyllable, rising and falling slur or falling and then rising slur. Call a startled, moderately high-pitched slightly squeaky "cheep".

Habitat. Hill and montane forest, moss forest and secondary forest. Nominate race at 1200–2150 m; *acrophila* apparently confined to summit of Mt Menawa (highest peak in North Coastal Range), from 1280 m to 1885 m.

Food and Feeding. Diet includes arthropods (insects), nectar and fruit. Forages from understorey to canopy, including crowns of flowering trees; gleans, and probes flowers.

Breeding. Female ready to lay in early Sept. No other information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species; present in North Papuan Mountains EBA. Poorly known; considered generally abundant within its altitudinal limits.

Bibliography. Beehler *et al.* (1986), Coates (1990), Coates & Peckover (2001), Diamond (1969, 1985), Hartert (1930), Rand & Gilliard (1967), Stattersfield *et al.* (1998).

123. Rufous-backed Honeyeater

Ptiloprora guisei

French: Méléphage à dos roux **German:** Rotrück-Honigfresser **Spanish:** Mielero Dorsirrojo
Other common names: Red-backed/Green-eyed/Guise's Honeyeater, Brown-backed Streaked Honeyeater

Taxonomy. *Ptilotis (?) guisei* De Vis, 1894, Mount Maneao, south-east New Guinea.

Formerly considered conspecific with *P. erythropleura*, *P. mayri* and *P. perstriata*, but the four differ in size, plumage (crown colour, dorsal coloration, colour of wing-covert edgings, distinctness of ventral spotting, flank colour) and iris colour. May form a superspecies with *P. mayri*, and often treated as conspecific with that species alone, but comparative studies indicate that the two are better considered separate species. Has sometimes been thought conspecific with *P. perstriata*, but the two occur sympatrically (with mutually exclusive altitudinal ranges) over at least 560 km in E New Guinea. Birds of Huon Peninsula intermediate between nominate and *umbrosa*, but closer to latter and generally included within it; populations of Adelbert Mts and Mt Bosavi likewise provisionally placed in *umbrosa*. W limits of nominate race uncertain; populations of Bismarck Range and Kubor Range placed in nominate, but may belong with *umbrosa* (or intergradient between the two races). Two subspecies recognized.

Subspecies and Distribution.

P. g. umbrosa Mayr, 1931 – Adelbert Mts, Mt Bosavi, Huon Peninsula (Saruwaged Mts), Schrader Range and Eastern Highlands (W at least to Tari), in NE & E New Guinea.

P. g. guisei (De Vis, 1894) – mountains of SE New Guinea, E from Bismarck and Kubor Ranges and Herzog Mts.

Descriptive notes. 16–18 cm; male 21–27 g and female 19–22 g (Huon Peninsula), male 21.3–27.7 g and female 17.6–24 g (Eastern Highlands). Nominate race has top of head and hindneck black with irregular olive to olive-grey streaking, merging to rufous-brown mottling on lower hindneck and lower side of neck; side of head blackish with grey streaking and wash, especially prominent on supercilium and around eye (rather "open-faced" expression); upperbody black to black-brown, mottled with rufous-brown, heavily so on mantle and scapulars and more diffusely and more weakly on rest of upperbody; upperwing and upperpart blackish-brown, pale olive to yellowish-olive margins on median coverts and outer edges of greater coverts, pale olive to olive-rufous outer edges of primaries; chin and throat light grey, diffusely mottled dusky; breast and belly largely pale grey to greyish-white

light blue, blue or blue-black (reported also as leaden grey), soles yellow. Sexes alike in plumage, male larger than female (latter c. 10% smaller). Juvenile is like adult, but duller and with more diffuse and weaker streaking above, and below washed olive-yellow to greenish-yellow, with reduced and duller rufous. Race *umbrosa* is slightly smaller than nominate, with crown streaking brownish-grey to light grey (not olive), somewhat duller brownish (less bright rufous) feather edges on upperbody. **Voice.** Varies locally and geographically, but all typically loud whistled notes usually repeated many times; heard throughout day. Typical vocalizations described as plaintive, high-pitched, lisp-like whistle of 2–3 notes "uree yooee" and variants. In SE, common calls include whistled "sieiew", and a slurred note followed by a falling note, "isiiep teuwp" or "siieei pup". In Eastern Highlands and Chimbu Province, calls include short staccato or buzzing note followed by plaintive slurred whistle, or the reverse; a whistled downslur followed by upslur; and a series of identical downslurred whistles (c. 1 note per second). Also staccato "chip". Wingbeats loud and conspicuous.

Habitat. Montane and upper montane primary forest, especially moss forest, also forest edge and secondary growth. Preference for moss forest, or its associated climatic conditions, shown by lower altitudinal limits of the species (linked to local variation in lower limits of moss forest): from c. 1340 m to 2500–2900 m in Central Ranges (replaced at higher altitudes by *P. perstriata*) and, on Iluon Peninsula, to tree-line at c. 3500 m (in absence of congener); mainly above 1800 m. Altitudinal overlap with *P. perstriata* of up to several hundred metres in some areas: on Mt Michael transition between the two occurs at 2890–3200 m, whereas on Mts Hagen, Kubor and Wilhelm transition at c. 2400 m.

Food and Feeding. Predominantly arthropods (mainly insects); also fruit, seeds (probably ingested with fruit) and nectar. Ranges from understorey to canopy, mainly in shrub layer and middle storey; occasionally visits flowering trees and shrubs (including *Xanthomyrtus papuanis*). Forages by gleaning and probing (epiphytes and flowers), and often hangs upside-down while foraging. Observed to steal nectar by probing pierced slits at bases of epiphytic *Rhododendron* flowers, although not seen to pierce the flowers. Active, conspicuous, and inquisitive. Usually singly, but often twos (probably pairs) mist-netted; sometimes associates with other species in flowering trees. Often adopts characteristic cocked-tail posture, and frequently flicks tail up.

Breeding. Few data. Nestling recorded early Feb and juvenile early May. Two nests found, 1.25 m and 2 m above ground in sapling (one a casuarina); another nest described as of this species, but suggested as more likely to be that of *P. perstriata*. Clutch apparently 1 egg; no information on incubation and nesting periods.

Movements. None known; presumed resident, possibly with some local movements.

Status and Conservation. Not globally threatened. Restricted-range species; present in Adelbert and Huon Ranges EBA and in Central Papuan Mountains EBA. Generally common to abundant in suitable habitat, e.g. on Mt Albert Edward, and in Simbai Valley; locally scarce to fairly common. The most abundant and characteristic species in moss forest in Eastern Highlands.

Bibliography. Beehler (1978a, 1980b), Beehler *et al.* (1986), Bell (1971a), Clapp (1996), Coates (1990), Coates & Peckover (2001), Coles (1995), Diamond (1969, 1973), Filewood (1969), Frith (1971), Frith & Frith (1992), Gilliard & LeCroy (1961, 1968), Gyldenstolpe (1955a), Heron (1977a), Hicks (1988d), Hicks & Burrows (1989, 1992), Lake (1958), Mayr (1931c), Mayr & Gilliard (1954), Mayr & Rand (1937), Rand (1936b), Rand & Gilliard (1967), Richards & Rowland (1995), Schönwetter & Meise (1981), Sims (1956), Stattersfield *et al.* (1998), Wahlberg (1988), Weston (1976a, 1977).

124. Black-backed Honeyeater

Ptiloprora perstriata

French: Méléphage strié **German:** Streifenhonigfresser **Spanish:** Mielero Estriado
Other common names: Grey-streaked/Many-streaked Honeyeater, Black-backed Streaked Honeyeater

Taxonomy. *Ptilotis perstriata* De Vis, 1898, Wharton Range, south-east New Guinea.

Formerly considered conspecific with *P. erythropleura*, *P. mayri* and *P. guisei*, but the four differ in size, plumage (crown colour, dorsal coloration, colour of wing-covert edgings, distinctness of ventral spotting, flank colour) and iris colour. Present species has sometimes been thought conspecific with *P. guisei*, but the two occur sympatrically (with mutually exclusive altitudinal ranges) over at least 560 km in E New Guinea. Sympatric (and with broad altitudinal overlap) also with *P. erythropleura* over distance of at least 400 km in W New Guinea. Proposed race *lorentzi* (described from Hellwig Mts, in Oranje Range) considered inseparable from nominate. Birds from Wissel Lakes area (between Weyland Mts and Snow Mts) described as race *incerta*, but validity uncertain, and thought possibly a hybrid between nominate race and *P. erythropleura* (of race *dammermani*); further study needed. Two subspecies currently recognized.

Subspecies and Distribution.

P. p. praedicta E. J. O. Hartert, 1930 – mountains of Wandammen Peninsula, in NW New Guinea. *P. p. perstriata* (De Vis, 1898) – New Guinea mountains from Weyland Mts and Nassau and Oranje Ranges E, including high peaks in Hindenburg, Victor Emanuel and Bismarck Ranges, to Wharton Range (in SE).

Descriptive notes. 19.5–20 cm; male 23.5–30 g and female 21–25.5 g (nominate), three males 29.5–32 g and one female 26 g (*praedicta*). Nominate race has head and neck black-brown, irregular light grey streaking on top of head, hindneck and side of neck, merging to dense fine pale grey streaking and speckling on side of head; upperbody black-brown to almost black, irregular light grey streaking on mantle merging to more olive-grey to pale olive-brown streaking on back and scapulars (whole of saddle appearing somewhat mottled); upperwing and upperpart dark brown, slightly browner than upperparts, median coverts and outer edges of greater coverts with rufous-brown tips, and rufous-brown basal outer edges on all except outer 2–3 primaries (which have faint rufous tinge on outer edges, apparently rapidly lost with wear); chin brown to dark brown, faintly mottled light grey, merging to light grey and diffusely brown-streaked on throat; underbody black-brown to dark brown or dark reddish-brown, heavily but irregularly streaked with light grey to off-white, and overlaid with strong rufous-brown wash on flanks, side of belly and vent and undertail-coverts; undertail olive-brown; underwing off-white to buff, mottled brown on coverts, with dark brownish-grey trailing edge

and tip; iris green to pale green or greyish-green; bill black; legs blue to blue-grey or leaden. Sexes alike in plumage, male larger than female. Juvenile is apparently largely dark brown to dark olive-brown and appearing unstreaked above (edges of feathers differing little from centres), heavily brown-streaked yellowish-olive below, lacking conspicuous rufous on flanks, with greyer chin and throat, also soft pale gape, brown (not green) iris, and greyish-brown legs. Race *praedicta* is larger than nominate (but highest-altitude populations of latter in Snow Mts more similar), has slightly paler ground colour on top of head, broader pale streaking on

crown to back and scapulars, greyer rump and uppertail-coverts, paler greyish-black to dark grey underbody with broader pale streaking, and paler and less extensive rufous-brown wash on flanks and sides. VOICE. Range of brief high-pitched and often slurred whistles, repeated every few seconds, such as “sueei-yu” (duration 0.75 seconds) and trisyllabic “ss’wei’ssii” (0.9 seconds) or “whee-u”, “wee dyu”, “a-whee”, “chee-a-wee”, “deeyur whit” or “peeyu seeyu”; also a loud, monotonously repeated upslurred “seeu”, a downslurred “seeee”, and continuous series of dry “chip” notes.

Habitat. Upper mid-montane and montane primary forest, from open to dense forest and including moss forest, at forest edge, tongues of stunted trees and shrubs extending into alpine grassland, and alpine and subalpine shrubland. From c. 1300 m to 3750 m in W New Guinea, fairly common above 1500 m in Ok Tedi region in C, but only above c. 2500 m in E. Largely above range of *P. guisei*, but altitudinal overlap of up to several hundred metres in some areas; on Mt Michael transition between the two occurs at 2890–3200 m, whereas on Mts Hagen, Kubor and Wilhelm transition was at c. 2400 m.

Food and Feeding. Diet includes arthropods (mostly insects), fruit and nectar. Forages from understorey shrubs, close to ground, up to canopy level; also commonly in shrubs of edge habitats. Takes insects and fruit by gleaning from foliage, twigs, branches and roots, probing moss and epiphytes, and occasionally sallying for flying insects; nectar, and probably some insects, taken by probing flowers, including of shrub *Dimorphanthera*, flowers of which it probed from below. Active and generally unwary; clammers about in vegetation and sometimes hangs upside-down. Usually seen singly, less often in twos (probably pairs); at least occasionally in mixed-species flocks.

Breeding. Eggs recorded in early Oct and late Jan (and almost certainly late Apr), nestlings early Jul, late Oct and early Nov (another nestling, probably of this species, in early Oct), fledglings early Sept and early Nov, and juveniles mid-Aug to mid-Sept; apparently carrying nesting material in early Feb. Nest a deep bulky cup, exterior made of moss, coarse grass, leaves and twigs and covered with live green moss (hangs from walls of nest), with some dry fine tendrils and green epiphytic orchid stems around upper rim, interior a cup of dry, paper-like pieces of *Pandanus* frond and *Nastus* bamboo leaves, lined thickly with hair-like plant fibres and feathers and fine hair, for three nests external diameter 10.5–11.6 cm, depth 11–14.5 cm, internal diameter 5–6.2 cm, depth 3.5–4.5 cm, another 9.5 × 12.5 cm externally and 5.5 × 3.5 cm internally; one nest suspended by rim from fork of sapling branch, another apparently supported on branch and against trunk of small tree, a third was atop a tree-fern (*Cyathea*) frond and another suspended by rim between horizontal forks, first three nests respectively 2.5 m, 5.5 m and 3.9 m above ground; nest originally described as that of *P. guisei* but more likely of present species was made of rootlets and dried leaves (of climbing bamboo), covered externally with living moss, lined with hair-like plant fibres and a few feathers, suspended from leafy fork of hanging vine; another nest probably of this species made of coarse grass, leaves and twigs, lined with feathers and grass, with strands of moss attached to exterior, external dimensions 11 × 13 cm. Clutch of 1 egg recorded (2 eggs possible); four nests each contained a single young, as also did nest originally described as that of *P. guisei*; no information on incubation and nestling periods.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in West Papuan Highlands EBA and in Central Papuan Mountains EBA. Not well known; considered generally fairly common to abundant.

Bibliography. Beehler *et al.* (1986), Coates (1990), Coates & Peckover (2001), Coles (1995), Diamond (1969, 1972a, 1973), Eastwood (1996a), Frith & Frith (1988, 1992), Gilliard & LeCroy (1961), Gregory (1995b), Gyldestolpe (1955a), Hartert (1930), Hopkins (1992), Loke (1958), Mayr & Gilliard (1954), Mayr & Rand (1937), McCarthy (2006), Melville (1980), Murray (1988b), Ogilvie-Grant (1915), Rand (1936b, 1942b), Rand & Gilliard (1967), Richards & Rowland (1995), Ripley (1964), Rowland (1995), Schönwetter & Meise (1981), Sims (1956), Stattersfield *et al.* (1998), Stein (1936), Weston (1977).

Genus GLICIPHILA Swainson, 1837

125. Tawny-crowned Honeyeater

Gliciphila melanops

French: Méléphage à calotte fauve **German:** Goldscheitel-Honigfresser **Spanish:** Mielero Coronado
Other common names: Fulvous-breasted/Fulvous-fronted Honeyeater

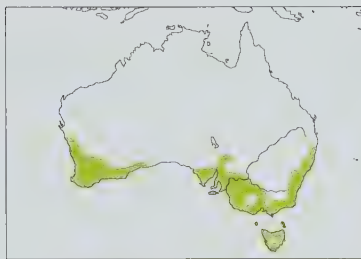

Taxonomy. *Certhia melanops* Latham, 1801, Nova Wallia Australi = New South Wales, Australia. Spelling of genus name sometimes emended to *Glyciphila*; currently awaiting official decision from ICZN. Until recently, genus subsumed in *Phylidonyris*. Formerly, birds from Kangaroo I were separated as race *braba* and those from Bass Strait islands and E Tasmania as *crassirostris*, but no significant differences from mainland birds. Two subspecies recognized.

Subspecies and Distribution.

G. m. melanops (Latham, 1801) – SW Western Australia (S from Kalbarri–Geraldton), E across S Australia (largely absent Nullarbor coast and Nullarbor Plain) to SE South Australia including Kangaroo I (and extending N through Flinders Ranges to Wilpena Pound), Victoria, and E coast of New South Wales (except far NE); also islands in Bass Strait (King I, Hunter Is, Furneaux Group; historical records in Kent Group), and E Tasmania.

G. m. chelidonia Schodde & Mason, 1999 – NW, W & SW coasts of Tasmania.

Descriptive notes. 14–18 cm; male 14.7–22 g, female 14–19 g (nominate). Nominat race is largely grey-brown above, streaked and mottled pale olive-brown on mantle, back and scapulars, and with distinctive head pattern of off-white forehead merging into rufous-brown to pale orange or ochre crown, bold white supercilium, black-brown facial stripe extending down side of neck to side of upper breast and enclosing small white crescent over rear ear-coverts, and white chin and throat; upwearing mostly dark brown, coverts with off-white to pale olive-brown margins, remiges with

narrow olive-yellow outer edges (diffuse pale panel on folded wing); uppertail dark brown, with fine white tip and side (in fresh plumage); underbody white, except for black-brown crescent at side of upper breast, grey-brown mottling on side of lower breast and belly, and grey-brown flanks; undertail grey-brown, underwing rufous-brown to salmon with grey-brown trailing edge and tip; iris dark brown; bill and gape black; legs grey-black to black. Sexes similar in plumage, male slightly larger than female. Juvenile differs markedly from adult, has head and neck brown, fine white streaking on top of head, hindneck and side of neck, diffuse whit-

ish crescent on rear ear-coverts, yellowish-white malar area, chin and throat, upperbody mostly brown, merging to pale olive-grey on rump, with bold white to pale brown streaking (except on rump), bolder off-white to buff margins on most wing-coverts, breast mottled brown and white, only hint of darker crescent at side, belly and vent off-white, rest of underbody pale grey-brown, bill black-brown or black with pale base of lower mandible, gape orange-yellow to yellow-brown. Race *chelidonia* differs from nominate in having distinct rufous tinge on mantle and upper back, and slightly rufous or buff tinge on side of breast and upper flanks. VOICE. Song, from perch and in flight, consists of simple, clear, plaintive bell-like or flute-like whistles, described as single drawn-out note followed by quick repetition of double note, and repeated 6–8 times, or ethereal high-pitched ascending “a-peer-peer-pee-pee-pee”; in spring often sings before dawn, and song a main component of dawn chorus. Other main vocalization a mournful drawn-out note, heard often. Other calls include “ciff, ciff, ciff” by female during distraction display, and undescribed distress calls.

Habitat. Primarily coastal and semi-arid inland heathland, preferring low (no more than 2 m tall) dry heathland with open structure, typically dominated by *Banksia* or *Allocasuarina* and with scattered emergent low trees or clumps of stunted trees (often *Eucalyptus* or *Angophora*). Also commonly in non-heath shrublands, and in Tasmania in buttongrass (*Gymnoschoenus*) sedge-land-moorland. Occasionally in mallee woodlands or shrublands, especially low dense heath-like mallee, but also in taller mallee with heathy or sparse understorey. Less often in low woodland of *Banksia* (or *Banksia* and stringybark eucalypts), open woodland or forest with heath or shrubby understorey, and dense low regrowth vegetation.

Food and Feeding. Mainly nectar, from wide range of plants (including *Banksia*, *Grevillea*, *Adenanthos*, *Xanthorrhoea*, *Astroloma*, *Correa*, *Eucalyptus*); also arthropods (mainly insects), and honeydew. Estimated ratio of nectar to insects in diet 42:58 near Adelaide (South Australia) and 68:32 at Golton Vale (Victoria); “insect” proportion at latter involved mostly honeydew. Forages in low shrubs, at flowers and among foliage; also much on ground, including among low grasses. Probes flowers for nectar; insects caught mainly by sallying, mostly sally-striking in air, but honeydew and some insects gleaned from bark, foliage or ground. Often shy. Usually singly, in twos or in small groups of up to ten individuals, but often appears to forage solitarily; sometimes gathers at food sources, but not in coherent flocks. At one site, many hundreds on one day fed on large influx of flying insects.

Breeding. Season Jul–Apr, clutches recorded mainly Aug–Nov (78.5% of 70 clutches) and nestlings Aug–Apr; in SW eggs Jul–Feb inland and Nov–Jan near S coast; in Sydney laying formerly coincided with flowering of *Boronia serrulata*, but nesting peak just N of Sydney coincided with flowering of *Banksia ericifolia*; possibly double-brooded if conditions suitable. Nest a deep cup made of shredded bark and grass, less often twigs, leaves, rootlets and spider web, lined with shredded bark, soft grass seeds and leaves, flowers, feathers and plant down, external diameter 8.3–11.4 cm, depth 7–8.9 cm, internal diameter 5.1–5.7 cm, depth 5.1–3.5 cm; suspended by rim or supported in fork or upright stems (including grasses and sedges), and usually woven into stems, normally low and well concealed in dense shrub or grass tussock, occasionally on ground, or up to 1.2 m (mean 0.3 m) above ground. Clutch usually 2 eggs, rarely 1 or 3 (4 eggs in one nest almost certainly involved laying by different females); incubation by female, period c. 13–16 days; chicks fed by both sexes, nestling period twice recorded as 12 days, and two 13-day-old young left nest on approach of human observer; fledglings fed by both parents. Nests parasitized by Horsfield’s Bronzeczuckoo (*Chrysococcyx basalis*) and Pallid Cuckoo (*Cuculus pallidus*).

Movements. Resident over most of range, with some seasonal patterns in occurrence or abundance. For example, at one site N of Sydney, present all months but densities lowest Nov–Feb; reporting rates in W Victoria indicate some movement between coastal and inland (more common on coast in Dec–Apr and inland May–Oct); in Wheatbelt of Western Australia, recorded throughout year but more often in winter than in summer. Considered nomadic or semi-nomadic at some sites, with occurrence irregular, though extent of movements not known and probably often only local. Occasional at some sites outside normal range, e.g. Eyre Bird Observatory (on Nullarbor coast), where recorded mainly May–Jul. Occasional influxes recorded, more often in W than in E; at Driptstone (New South Wales) large flock appeared in Jun and disappeared within two days. In W range, suggested that some seasonal movements related to flowering of plants, although near Albany more common when nectar scarce than when abundant (possibly because excluded by other honeyeaters). Influxes sometimes coincide with flowering of foodplants, sometimes with drought.

Status and Conservation. Not globally threatened. Fairly common; recorded densities of 0.05–1.6 birds/ha at various sites. Range and numbers have decreased at some sites as a result of habitat clearance, such as in Wheatbelt of Western Australia. In urban E Sydney, population reduced to a few pairs by late 1960s and extirpated by 1971.

Genus CISSOMELA Bonaparte, 1854

126. Banded Honeyeater

Cissomela pectoralis

French: Méléphage à collier **German:** Brustband-Honigfresser **Spanish:** Mielero Bandeado

Other common names: Banded Myzomela

Taxonomy. *Myzomela pectoralis* Gould, 1841, Kimberley Division, Western Australia. This species and *Sugomel nigrum* often placed in genus *Certhionyx* because of similarities in external appearance to *Certhionyx variegatus*; DNA-sequencing studies, however, indicate that the three species are unrelated. Monotypic.

Distribution. N Western Australia (S to about Broome, including a few inshore islands, e.g. Sir Graham Moore, Boongaree and Sunday I) E through Top End of Northern Territory (S to Barkly Tableland) to N Queensland (S to Atherton Tableland–Burdekin R–Hughenden).

Non-breeding plumage similar, but mantle, back and scapulars varying brown (ranging from light brown with bold black streaking to black with scattered small patches of light brown); gape yellow. Sexes alike in plumage, male larger than female. Juvenile is like adult but duller, cap pale brown, upperbody largely light rufous-brown, rump grey with faint rufous-brown wash, lores grey-black and ear-coverts washed pale yellow (small blackish spot on lower rear coverts), upperwing and uppertail black-brown, wing-coverts and tertials with broad light rufous-brown fringes, narrower edges on remiges (contrasting panel on folded wing), light brown edges on rectrices (soon lost), underbody faintly tinged cream, narrow pale brown breastband, buff-white underwing with dusky patch on primary coverts and dark grey trailing edge and tip, gape-flanges yellow and initially swollen, and iris paler (sometimes grey-brown). Voice. Buzzing call notes, given constantly; high-pitched double whistle; single loud whistle, sometimes in repeated series. Song, from perch and in song flight, a short, clear tinkling or twittering; partners also sing poorly co-ordinated antiphonal duets, consisting of series of 2–5 calls by one bird and repeated by mate. Also soft song during courtship display.

Habitat. Mainly open or savanna eucalypt woodlands or forests, dominated by such species as variable-barked bloodwood (*Eucalyptus dichromophloia*), Darwin box (*Eucalyptus tectifica*), Darwin stringybark (*Eucalyptus tetradonta*) and Darwin woollybutt (*Eucalyptus miniata*), with ground cover of dense, tall grasses dominated by *Sorghum*, *Heteropogon*, *Allotriopsis* and *Themeda*, or of spinifex (*Triodia*), and with sparse or no shrub layer. Also often in open or closed riparian paperbark (*Melaleuca*) forest, especially of weeping paperbark (*Melaleuca leucadendra*), sometimes mixed with *Lophostemon* and eucalypts, and with thickets of *Pandanus*. Sometimes in patches of monsoon rainforest or in mangroves; occasionally in thickets of mixed lancewood–bullwaddy (*Acacia shirleyi*–*Macropteranthus keckwickii*) woodland, and in tropical heathland, mixed broadleaf woodland and wet sclerophyll forest; also in urban gardens.

Food and Feeding. Mainly nectar; also arthropods (mainly insects, also spiders), and seeds. In NW Australia, seen to feed on flowers that provided best source of nectar. Forages in crowns of trees, less often in subcanopy and shrub layer; mostly among flowers and in outer and inner foliage, sometimes on branches in upper levels, on trunks, or in air. Probes flowers for nectar; most insects taken by gleaning, sometimes by sally-hovering or flutter-chasing. Active. Usually in twos or in small to large parties of 5–20 or up to hundreds of individuals, rarely singly; sometimes in large numbers in flowering trees, particularly paperbarks, e.g. at least 1000 in flowering paperbarks and 200 or more in flowering eucalypts. Sometimes in mixed-species flocks, e.g. with other meliphagids.

Breeding. Season Nov–Jul/Aug, with eggs or laying recorded Nov, Feb–Mar, May and Jul. Nest small and cup-shaped, made of grass, strips of bark, twigs and plant fibre, bound with spider web, usually lined with fine grass, external diameter 3.8–5.6 cm, depth 2.5–4.8 cm, internal diameter 3.8–5 cm, depth 3–4.4 cm; suspended by rim from thin fork of branch 0.45–5.2 m (mean 2.1 m) above ground, usually in outer foliage of shrub or small tree. Clutch usually 2 eggs; incubation by female, both parents feed nestlings and fledglings; no information on duration of incubation and nestling periods.

Movements. Not well known. Widely described as nomadic or dispersive. Abundance or occurrence appears seasonal at some sites, e.g. visits Atherton Shire (NE Queensland) in Aug–Dec; and at other sites present throughout year. Numbers and apparent movements often related to flowering of foodplants, birds arriving when trees in flower and leaving when flowering finished. Influxes sometimes occur where large patches of trees are in flower. Vagrant in Torres Strait (Goode I) and, far to S, in New South Wales (Greenwell Point).

Status and Conservation. Not globally threatened. Common to locally common. In Northern Territory, recorded densities of 0.2–1.6 birds/ha in Kakadu National Park; and in Yinberrie Hills, NW of Katherine, mean of 3.35 birds/ha, with maximum density of 17.9 birds/ha at start of wet season.

Bibliography. Genus *LICHMERA* Cabanis, 1851

127. Scaly-crowned Honeyeater

Lichmera lombokia

French: Méléphage de Lombok **German:** Lombokhonigfresser **Spanish:** Mielero de Lombok
Other common names: Sunda/Lombok Honeyeater

Taxonomy. *Meliphaga lombokia* Mathews, 1926, Lombok. Originally described as *Ptilotis virens*, but that name invalid, as preoccupied. Forms a superspecies with *L. argentauris*. Has been suggested that ecological and slight morphological differences exist

between populations of Lombok and those of Sumbawa and Flores (slightly darker), and latter sometimes separated as race *fumidigula* (type locality Flores); morphological differences, however, considered trivial (especially in view of changes in appearance with wear and fading of plumage), and supposition of ecological differences possibly in error; study needed. Proposed race *narmadae* (from Lombok) is a synonym of the name *lombokia*. Treated as monotypic.

Distribution. Lombok, Sumbawa and Flores, in W Lesser Sundas.

to bluish-grey. Sexes apparently alike in plumage, male probably larger than female. Juvenile undescribed. Voice. Short, unmusical nasal downslurs, typical of honeyeater; also, short series of rapidly repeated, semi-sweet chattering notes.

Habitat. Primary forest and degraded forest, including upper montane semi-evergreen forest and lower montane forest, forest edge, scrub, lightly wooded agricultural land, and in gardens. More common at higher elevations, sometimes absent at lower levels. Sea-level to 1600 m or above, mainly above 800–1000 m (some authors state mostly below 1000 m), on Lombok; only above 800 m on Sumbawa; 700–2140 m, mainly above 1000 m, on Flores. In recent surveys on Flores and Sumbawa, common at all montane sites and generally more common with increasing altitude.

Food and Feeding. No details of diet. Occurs from substage to lower canopy; will forage in fruit trees. Seen singly, in twos (probably pairs) and, often, in small groups of up to ten individuals; also often in mixed-species flocks.

Breeding. No information.

Movements. No information; probably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Nusa Tenggara EBA. Common at all montane sites in recent surveys on Flores and Sumbawa. Not considered under threat on these two islands, where extensive forest remains within its altitudinal range. Creation of a protected area of montane forest and mid-altitude rainforest suggested as being of high priority for conservation of high-altitude species, including present species. No information from Lombok.

Bibliography. Brooks & Butchart (1993), Butchart *et al.* (1996), Coates & Bishop (1997), Johnstone *et al.* (1996), Mees (2006), Myers & Bishop (2005), Rensch (1931a), Stattersfield *et al.* (1998), Trainor (2002a), Verhoye & Holmes (1999), Wallace (1863), White & Bruce (1986).

128. Olive Honeyeater

Lichmera argentauris

French: Méléphage à joues argent **German:** Silberohr-Honigfresser **Spanish:** Mielero Cariplateado
Other common names: Plain Olive/Silver(-spangled) Honeyeater

Taxonomy. *Ptilotis argentauris* Finsch, 1870, “Neu Guinea und die Papu-Inseln” = Waigeo, West Papuan Islands.

Forms a superspecies with *L. lombokia*. Birds from Halmahera, Damar and Gebe sometimes separated as a geographical race, *chloris* (described from Gebe I), but morphological differences considered insignificant; birds on Lusaolale I (off N Seram) described as race *pataisiwa*, but unlikely to be distinct and species not resident on this island. Treated as monotypic.

Distribution. Halmahera, Damar, Gebe, West Papuan Is (Waigeo, Schildpad, Misool), Lusaolale I (off N Seram) and almost certainly Seram.

nile undescribed. Voice. A harsh “zhip”.

Habitat. Occurs among coastal trees, palms and scrub, including littoral stands of casuarina and coconut palms.

Food and Feeding. Diet includes nectar and apparently fruit. Forages in casuarinas, at flowers of coconut palms and papaya (*Carica*) trees, and in fruiting trees. Seen singly, in twos (probably pairs) and in small groups; flock of 40 birds once recorded.

Breeding. No information.

Movements. Mainly resident; only isolated records on Lusaolale, where probably not resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA, in Northern Maluku EBA and in West Papuan Lowlands EBA. Not well known; described as generally rare and local in Wallacea. Assumed presence on Seram based on observation of a single individual which flew from Lusaolale I towards Seram (c. 1 km distant).

Bibliography. Beehler *et al.* (1986), Bowler & Taylor (1989a, 1993a, 1993b), Coates & Bishop (1997), Poulsen & Lambert (2000), Rand & Gilliard (1967), Stattersfield *et al.* (1998), Stresemann (1914a), White & Bruce (1986).

129. Indonesian Honeyeater

Lichmera limbata

French: Méléphage frangé **German:** Balihonigfresser **Spanish:** Mielero Indonesio

Taxonomy. *Meliphaga (Ptilotis) limbata* S. Müller, 1843, Timor.
Forms a superspecies with *L. indistincta* and *L. incana*; often treated as conspecific with former. Monotypic.
Distribution. Bali, and Lesser Sundas on Lombok, Sumbawa, Sangeang, Komodo, Flores, Lomblen, Alor, Sumba, Savu, Roti, Ndao, Ndao, Semau and Timor (including Atauro I).

brown trailing edge and tip; iris dark brown; bill and gape black; legs grey. Female is like male but smaller, has chin and throat yellowish-olive to dirty yellow (colour possibly curving up onto side of neck behind ear-coverts), rest of underbody tinged yellowish, and top of head concolorous with upperparts; bare parts possibly differ, with pale yellow gape and base of lower mandible (confirmation needed). Juvenile not fully described, like female but slightly browner above and below, with yellow wash on face (as well as chin and throat), and with no or only trace of yellowish tuft behind eye, bare parts presumably differ (e.g. pale bill base, swollen yellow gape). VOICE. Variety of moderately loud staccato notes, whistles, and harsh chatters; alarm call described as harsh grating. Song sweet and strong, can be given in long continuous bursts, once for c. 75 seconds.

Habitat. Monsoon woodland, mangroves, secondary growth, open woodland (e.g. dry thorny woodland on Komodo) and savanna, forest and forest edge, scrub and riparian vine scrub along creeks, also semi-cultivation and cultivation, coconut groves and plantations, and parks and gardens in towns and villages. On Lomblen, recorded in swamp-forest, a closed forest of diverse floristics to 25 m tall, and coastal complex vegetation (a mix of human-modified habitats in coastal lowlands) from sea-level to c. 100 m, including coconut plantations, grassland and shrubland. On Alor, significant preference for *Eucalyptus* savanna over rainforest. Mainly at higher elevations on Lombok (sea-level to 2600 m, mainly 800–1200 m) and Sumbawa (sea-level to 1000 m, mainly above 800 m), but mainly coastal on Sumba (to 950 m, mainly below 400 m), Timor (to c. 150 m) and Atauro I (to 800 m); at all altitudes, particularly higher altitudes, on Bali. In E Flores, what is thought to be this species occurs mainly above c. 1000 m.

Food and Feeding. Diet includes nectar, and presumably insects. Forages at flowering trees and shrubs. Active, noisy and aggressive; acrobatic. Usually seen singly, in twos (probably pairs) and in small groups.

Breeding. Nestling on Roti in mid-Apr. No other information.

Movements. Resident on Sumba and Lomblen; probably resident, with some local movements, throughout range.

Status and Conservation. Not globally threatened. Locally common to moderately common on Lombok, Sumbawa, Sangeang (off NE Sumbawa), Sumba and Timor; abundant on Atauro I; not uncommon to very common or locally abundant on Bali. Generally uncommon in rest of range.

Bibliography. Bishop (1992), Bruce (1987), Coates & Bishop (1997), Conole (1997), Johnstone & Jepson (1996), Johnstone *et al.* (1996), Jones *et al.* (1990), Linsley *et al.* (1999), MacKinnon & Phillips (1993), Mayr (1944a), Mees (1975, 1982, 2006), Myers & Bishop (2005), Rensch (1931a), Trainor (2002c, 2005a, 2005b), Trainor & Soares (2004), Verhoeve & Holmes (1999), White & Bruce (1986).

130. Brown Honeyeater

Lichmera indistincta

French: Méléphage brunâtre **German:** Braunhonigfresser **Spanish:** Mielero Pardo
Other common names: Australian Brown/Least/Warbling Honeyeater

Taxonomy. *Meliphaga indistincta* Vigors and Horsfield, 1827, King George Sound, south Western Australia.

Forms a superspecies with *L. limbata* and *L. incana*. Race *ocularis* intergrades with nominate through SE Gulf of Carpentaria Drainage. Four subspecies recognized.

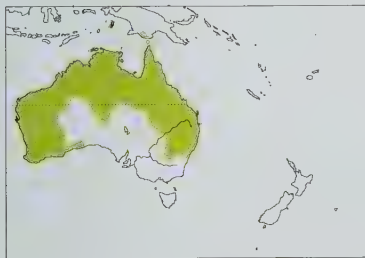

Subspecies and Distribution.

L. i. nupta (Stresemann, 1912) – Aru Is.

L. i. melvillensis (Mathews, 1912) – Tiwi Is (Bathurst I, Melville I), off N Northern Territory (N Australia).

L. i. indistincta (Vigors & Horsfield, 1827) – Western Australia (E to fringes of deserts and, in S, along coastal fringe S of Nullarbor Plain to about Eyre) and Northern Territory (S to C ranges) E to SE Gulf of Carpentaria and NW Queensland (Selwyn Range), and CN South Australia.

L. i. ocularis (Gould, 1838) – S New Guinea (S Trans-Fly region, including around Merauke, Bensbach R and L Daviambu), Saibai I (in N Torres Strait) and E Australia from Cape York Peninsula S to SW Queensland and CN & CE New South Wales (S to around Sydney).

larger coverts; below, brownish-grey on breast, merging to dirty brownish-white on rest of underbody; undertail grey-brown or olive-brown; underwing off-white with grey-brown trailing edge and tip, yellow tinged on leading edge at angle of wing; iris dark brown; bill black, gape black when breeding, pale yellow at other times; legs grey-black. Female is smaller than male, differs also in having forehead and crown concolorous with upperparts; gape always pale yellow. Juvenile

is like female, but slightly paler and browner upperparts, no (or minute) yellowish tuft behind eye, pale yellow wash on lower underbody, black-brown bill with pink-grey base, bright yellow and swollen gape. Races differ only subtly: *ocularis* is similar in size to nominate, but male significantly longer-billed (and said to be larger than nominate at equivalent latitudes), male cap slightly darker, contrasting more with hindneck and side of head, olive margins on wing and tail feathers bolder and brighter, and throat and breast slightly darker; *nupta* is like previous but darker above, lacks yellow postocular tuft, has larger area of bare skin around eye; *melvillensis* is similar in size to nominate, but male has significantly longer bill and female significantly shorter tail, male differs further in slightly darker upperparts, with little contrast between top of head and hindneck, stronger and brighter olive margins on wing and tail feathers, and darker throat and breast, female very similar to male (sexes indistinguishable in field). VOICE. Noisy, calls throughout year (apparent seasonal peaks, e.g. vocal activity in Western Australia greatest Aug–Dec), also throughout day, most frequently in early morning. Song a very loud, rich, liquid, rolling phrase but with somewhat harsh tone, rendered as “sweet-sweet-quarty-quarty”, possibly has territorial function; similar to song of Australian Reed-warbler (*Acrocephalus australis*). Calls include harsh “ke-ke” given several times at intervals of 1 second, or variant of single “ke”, varying in length; a loud “plik” (New Guinea) and series of “plink” notes, from prominent perch, and sometimes answered with song from bird in dense low vegetation (Australia). Snaps bill in aggressive interactions.

Habitat. Throughout range occupies wide range of habitats, often near water, including watercourses, swamps, billabongs, waterholes, bores, springs, tanks and drainage-lines. In Australia, commonly in mangrove forests, woodlands or shrublands along tidal flats, creeks, estuaries and shorelines, and in ecotone between mangrove and other coastal forests, woodlands and shrublands, such as those dominated by *Banksia*; commonly in dense forests, woodlands or thickets of paperbarks (*Melaleuca*), and in closed and open sclerophyll forests and woodlands dominated by *Eucalyptus* (including mallee eucalypt woodlands and shrublands), by *Acacia* e.g. of mulga (*Acacia aneura*), gidgee (*Acacia cambagei*) and brigalow (*Acacia harpophylla*), or by casuarinas, *Grevillea* or *Hakea*; also often in riparian associations with flowering *Callistemon*, or riparian thickets of *Pandanus* (especially mixed associations with eucalypts); less often in low, dense habitats, including heathland, sedgeland, fernland, saltmarsh and coastal scrub. On Arnhem Land islands (N Northern Territory), most abundant in tropical heathland dominated by *Grevillea pteridifolia*, *Asteromyrtus symphyocarpa*, *Calytrix*, *Acacia* and spinifex (*Triodia*). In Northern Territory occurs in subcoastal and lowland monsoon forest or rainforest (though less so in these habitats elsewhere), and in ecotone between open eucalypt forest and monsoon forest; occasionally in coastal tussock grassland. Commonly in suburbs, towns and around homesteads, in parks, gardens and streets; and in remnant vegetation along roads or in farming land. In New Guinea mainly in low, open *Banksia* savanna, but also other open savannas, open monsoon woodland and edges of rainforest; also forages in flowering mangroves and paperbarks. Mainly near sea-level in New Guinea.

Food and Feeding. Mainly nectar; also small invertebrates, mainly insects, also spiders (Araneae). Nectar frequently of *Banksia* or *Eucalyptus*, also *Dryandra*, *Adenanthos*, *Calothamnus*, *Grevillea*, *Melaleuca*, and mangroves (including *Rhizophora*, *Bruguiera*, *Ceriops*, *Avicennia* and *Lumnitzera*); in various studies, proportions of observations of nectar-feeding 56–99%. Forages at all levels, from crowns of trees to shrub layer and ground, also in air; mainly at flowers or among foliage or branches in inner and outer canopy, also in flowering or fruiting mistletoes (Loranthaceae), on trunks of trees, on palm fronds, in saplings and on twigs. Obtains nectar mainly by probing flowers, occasionally sally-hovering; sometimes hangs below branch to probe for nectar from pendulous *Eucalyptus* flowers. At one site in Western Australia, nectar available all year but some plants probed more often than others, and preferred species possibly changes during day. Insects mostly gleaned from foliage and bark; sometimes caught by sallying (including sally-striking in air, sally-striking at hard substrate, such as foliage and twigs, and sally-hovering) or by flutter-chasing (moving rapidly through vegetation, disturbing and pursuing prey). Active and usually conspicuous, but can be unobtrusive. In Australia and New Guinea usually singly or in twos (probably pairs), sometimes in small groups of up to 10–20 individuals in flowering trees. Occasionally in mixed-species flocks with other meliphagids. Sometimes aggressive.

Breeding. In New Guinea birds said to be in breeding condition in Aug–Sept, but no other information. All following details refer to Australia. Breeding recorded in all months (91% of 120 clutches May–Nov), but season appears to vary, with breeding and clutches mainly late autumn to late winter (dry season) in N Australia, and winter to summer or early autumn in E & S. Nest built by female alone or by both sexes, a rounded or elliptical and open cup of small pieces of grass and bark, sometimes paper or leaf skeletons, bound or woven with spider web, less often wool, hair or plant fibre, usually lined with plant down or, less often, fine grass, hair, downy seeds or flowers, and spider egg sacs or cocoons sometimes attached to exterior (and sometimes leaves of nest plant incorporated into sides), external diameter 5–7.6 cm, depth 3.8–6.4 cm, internal diameter 3.4–5.1 cm, depth 2.9–4.6 cm (elliptical nests had external length and breadth of 5.3–6.6 × 4.3–5 cm); typically well concealed in dense outer foliage or twigs, less often close to trunk, in crown of tree or in shrub (often mangrove, eucalypt or paperbark), sometimes in grass-tree (*Xanthorrhoea*), dense vines, mistletoe or epicormic growth, occasionally in loose bark, in fallen tree or branch, or among rushes (*Typha*) or ferns, often near water and usually low, 0.03–7 m (mean 1.3 m) above ground. Clutch 1–3 eggs, mostly 2 (mean 1.94); incubation apparently by female only, period 13–14 days, possibly 12–15 days; chicks evidently brooded by female alone and fed by both sexes, nestling period 13–17 days. Nests parasitized by Brush (*Cacomantis variolosus*) and Pallid Cuckoo (*Cuculus pallidus*), Horsfield’s Bronze-cuckoo (*Chrysococcyx basalis*) and possibly Shining Bronze-cuckoo (*Chrysococcyx lucidus*). From 113 eggs in 57 nests, 0.49 fledged young per nest; of 96 nests at which outcome known, 43.8% fledged at least one young.

Movements. Resident in many areas; also widely described as nomadic or partly nomadic, but extent of any such movements not known, and possibly mostly local. Suggested as being resident or moving only locally in areas of high or regular rainfall, but that elsewhere movements related to flowering of foodplants; aforementioned local movements, however, probably also linked to flowering, and again no understanding of extent of movements. In study at Wongamine Nature Reserve, in Western Australia, maximum numbers coincided with peak in number of *Banksia* inflorescences. In many regions, sedentary populations probably augmented by influxes of birds in response to flowering of foodplants, causing fluctuations in numbers; in ringing study in SE Queensland, major influxes consisted almost entirely of juveniles. Considered a seasonal visitor or migrant in some areas, e.g. at Meandarra (SE Queensland) recorded mostly Mar–Aug and few records at other times; few reports from N South Australia, all except one in Jun–Nov; and in SW Australia winter visitor Jul–Oct at Albany. Irregular visitor at other sites, usually associated with flowering events (although no analysis of flowering without presence of honeyeaters). Vagrants and occasional irruptions recorded in areas well beyond normal range.

Status and Conservation. Not globally threatened. Locally common but generally scarce in New Guinea; on Fly R, sex ratio recorded during one survey strongly male-biased. Common to abundant in Australia, and recorded at mean densities of up to of 2.31 birds/ha. In study in SW Australia, equally common in vegetation of road verges, wandoos (*Eucalyptus wandoo*) woodland with understorey and agroforestry sites, and significantly more abundant than in wandoos woodland without understorey and reforested sites. Declined in Wheatbelt of SW Australia after large-scale clearing.

Bibliography. 131. Dark-brown Honeyeater

Lichmera incana

French: Méliphage à oreillons gris **German:** Grauhör-Honigfresser **Spanish:** Mielero Orejigris
Other common names: Grey-eared/Loyalty (Islands)/Silver-eared(!) Honeyeater

Taxonomy. *Certhia incana* Latham, 1790, New Caledonia.
Forms a superspecies with *L. limbata* and *L. indistincta*. Five subspecies recognized.
Subspecies and Distribution.
L. i. griseoviridis Salomonsen, 1966 – C Vanuatu, including Malakula, Ambrym, Paama, Lopévi, Epi, Tongoa, Tongariki, Emae, Makura, Mai, Nguna and Éfaté.
L. i. flavotincta (G. R. Gray, 1870) – Erromango, in S Vanuatu.
L. i. poliotis (G. R. Gray, 1859) – Beautemps Beauré, Ouvéa and Lifou, in Loyalty Is.
L. i. marensis Salomonsen, 1966 – Maré, in Loyalty Is.
L. i. incana (Latham, 1790) – New Caledonia.

breast and upper belly and paler on lower underbody; undertail olive-brown, faint olive tinge at edges of rectrices, underwing off-white with silvery brownish-grey trailing edge and tip; iris brown to pale grey-brown to dull dark brown; bill black; legs mid-grey to brown. Sexes alike in plumage, male noticeably larger than female. Juvenile is slightly paler and duller than adult, lacking conspicuous silvery ear-patch, and with prominent yellow to yellow-orange gape. Races differ only slightly: *flavotincta* is larger than nominate, darker grey-brown on chin, throat and breast with less olive tone; *griseoviridis* is slightly larger than nominate, and with darker grey-brown chin, throat and breast (although some almost indistinguishable from nominate); *marensis* is much smaller than previous, and paler grey below, with stronger yellow tinge on lower breast and belly; *poliotis* is very similar to last in size and plumage, paler grey below with little or no olive tinge. **Voice.** Noisy, with vocalizations described as cheery or pleasing; most vocal in morning and evening, and one of first birds to call, well before dawn. Main call a loud, harsh “tchoo-tchoo-tchoo”; also “cheelp-cheelp” like chirp of sparrow (*Passer*); short, musical warbling song. Said to mimic other species.
Habitat. Widespread and common in all habitats except humid forests and open fields: primary and secondary forest, forest edge, mangroves, scrub, gardens in villages and towns and other urban areas, and agricultural landscapes, particularly coconut plantations. Also niaouli (*Melaleuca leucadendra*) savanna woodland in New Caledonia. Sea-level to lower hills.
Food and Feeding. Nectar, pollen, fruit, also small arthropods (including insects, spiders). Feeds on wide range of flowering plants, but on Vanuatu shows strong preference for flowering coconut palms, which available all year; in gardens, seen to feed at flowering hibiscus, banana, lantana and ornamental ginger (*Zingiberaceae*). Forages from canopy to shrub layer, seeking flowers and searching for arthropods on leaves and branches, clambering about and hanging in all positions. Appears to forage mainly by gleaning (including from underside of leaves) and probing. Sometimes sally-hovers to take nectar from flowers or to take trapped insects from spider webs, or sallies for flying insects. Large insects may be bashed against perch to stun or kill them, or perhaps to remove limbs. Constantly active, noisy and conspicuous. Usually singly or in twos (which appear to be pairs); also in groups of 10–30 individuals in preferred flowering trees, where it will forage throughout day, often with *Myzomela cardinalis*, white-eyes (*Zosterops*) and lorikeets (*Charmosyna*, *Trichoglossus*).
Breeding. Season protracted, but few data for timing of laying or nestlings: in New Caledonia normally Oct/Nov–Jan, but earlier statements claim nestlings in Jun–Jul (as well as Nov) and two peaks of breeding in year (confirmation needed); in Vanuatu normally Oct–Feb, but eggs recorded on Tongoa late Aug and early Sept and nests with young as early as Jun, probably several broods in a year. Extent of territoriality not certain; stated as territorial throughout year, and pair said to defend area from conspecifics for years, but described also as territorial only when breeding, defending only area around nesting tree. Nest apparently built by both sexes, a small, deep cup made of grass, other plant fibres, a few small leaves and spider web, lined with feathers at bottom, often fine (eggs visible through nest), external diameter at least 5.5 cm, internal diameter 4–5.5 cm, suspended by rim from fork of thin branch at height of 2–12 m in shrub or tree. Clutch usually 2 eggs (clutches of 1 reported); incubation allegedly by both sexes (unusual, confirmation needed), period 14 days; chicks fed by both parents, nestling period 12 days; fledglings fed by both adults.
Movements. Sedentary; local movements to flowering plants.
Status and Conservation. Not globally threatened. Restricted-range species: present in Vanuatu and Temotu EBA and in New Caledonia EBA. Common and widespread throughout its range. In Vanuatu, possible sight records on Espiritu Santo claimed in 1944, but there appear to be no other reports from that island; said to have been recorded on Tanna (S Vanuatu) in 1879, probably in error.

Bibliography. Bregulla (1992), Delacour (1966), Diamond & Marshall (1976), Doughty *et al.* (1999), Hannecart & Létocart (1980), Layard & Layard (1878, 1880, 1882), Mayr (1932, 1937, 1938, 1945b), Medway & Marshall (1975), Myers (2004), Parker (1967), Ross (1988), Salomonsen (1966a), Scott (1946), Stattersfield *et al.* (1998), Stokes (1980), Tristram (1879).

132. Scaly-breasted Honeyeater

Lichmera squamata

French: Méliphage à plumet blanc **German:** Salvadorihonigfresser **Spanish:** Mielero Escamoso
Other common names: White-tufted/Scaly/Scaled/Tanimbar/Banda Sea/Mottle-breasted Honeyeater

Taxonomy. *Stigmatops squamata* Salvadori, 1878, Choir Island = Koer Islands, east Banda Sea. Forms a superspecies with *L. alboauricularis*. Populations of Tanimbar Is sometimes separated as geographical race *salvadorii* (type locality Timorlaut) and those from elsewhere in E Lesser Sundas as *kebiensis* (type locality Babar I); study needed. Treated as monotypic.
Distribution. Tayandu Is (Ree, Tayandu), Koer Is (Kilsoein), Manggoer, Fathol, Taam, Kai Is (Kai Besar, Er) and Godan I, in SE Moluccas, and Wetar, Romang, Damar, Leti, Moa, Luang, Sermata, Babar and Tanimbar Is (including Larat, Loetoe and Moloe), in E Lesser Sundas.

Descriptive notes. 14.5 cm; one female 13 g, one unsexed 13 g. Plumage is olive-grey above, with paler olive to yellow-olive rump and uppertail-coverts; distinctive facial pattern of largely bare blackish-brown to black skin covering lores and narrowly above eye and broadly below and behind eye, finely speckled with small, stiff white feathers (sparsely on lores, more heavily below and behind eye in radial pattern) merging into small silvery white to greyish-white triangular or crescent-shaped patch on upper rear ear-coverts (at least sometimes finely speckled black), this bordered above by diffuse blackish line extending from upper rear of blackish facial patch; pale grey submoustachial stripe and lower ear-coverts, bordered below by black malar stripe; upperwing largely olive-grey, as back, with brownish-grey inner webs of remiges and diffuse paler tips on some outer coverts; chin and throat off-white to yellowish-white; underbody appears to vary (not known whether variation sex-related or age-related or geographical) from off-white to pale yellowish-olive, grading to bright yellow on belly on some, and with distinctive blackish-olive “rosethorns” across breast fading onto belly and flanks, petering out to dirty streaks or mottling on lower flanks and undertail-coverts; undertail greyish-brown; iris yellowish-grey to dark brown or red-brown; bill black; legs grey. Sexes alike in plumage, male larger than female; gape of one female described as yellow, but photos of adults of unknown sex have black gape; whether gape varies sexually, or seasonally (as with nominate *L. indistincta*), not known. Juvenile is like adult, but underparts olive-grey with only faint or obsolete scaling, and with bare pinkish spot behind eye. **Voice.** On Wetar, calls include downslurred whistled “chirrup” or upslurred “chirrup” or “chisip” of moderate pitch, repeated at intervals of 2–10 seconds; loud descending trill of moderate pitch and slowing towards end, “teu, tututututututututututu-tu”, lasting c. 5 seconds; repeated “whitcheo whitcheo, whitcheo whitcheo” (at rate of 1.6 notes per second); rapidly repeated, sharp and somewhat harsh whistling “tsi-tsi-tsi-tsi...” or “tchi-tchi-tchi-tchi...” in bouts of varying duration (at rate of 6.5 notes per second); and series of 5 rapid whistles of same pitch and volume, lasting c. 1.2 seconds.
Habitat. Coastal and lowland secondary monsoon woodland, open scrub and shrubland, mangroves, lightly wooded agricultural land, coconut plantations and trees, forest edge, and villages with scattered trees. Less often in primary forest and in selectively logged semi-evergreen forest.
Food and Feeding. Nectar and, presumably, insects. Occurs from substage to canopy. Forages at flowers, including of coconut palms and inconspicuous flowers in canopy and middle storey; also gleans from undersides of leaves. Noisy and conspicuous. Seen singly, in twos (probably pairs) and in small groups of up to six individuals; occasionally with mixed-species flocks.
Breeding. Nest is neat structure, decorated on outside with cobwebs, wool and cotton, with entrance to side, sometimes with partial roof, and tail hanging down from below. Clutch 2 eggs. No further relevant information.
Movements. Little information; considered resident in Tanimbar Is.
Status and Conservation. Not globally threatened. Restricted-range species: present in Timor and Wetar EBA and in Banda Sea Islands EBA. Generally common to abundant; one of the commonest bird species on Yamdena and Damar. Rare on Terbang Utara and Terbang Selatan, two islets (each 56 km² in extent) lying, respectively, c. 10 km and c. 15 km S of Damar.
Bibliography. Bishop & Brickle (1999), Coates & Bishop (1997), Gadow (1884), Hartert (1900b, 1901), Lewis (1993), Schodde & Mathews (1992), Schönwetter & Meise (1981), Stattersfield *et al.* (1998), Trainor (2002d, 2007b), Verbeek (1996), White & Bruce (1986).

133. Silver-eared Honeyeater

Lichmera alboauricularis

French: Méliphage grivelé **German:** Ohrflecken-Honigfresser **Spanish:** Mielero Pechipinto
Other common names: Eared/Freckled/White-eared(!)/White-spangled Honeyeater

Taxonomy. *Stigmatops albo-auricularis* E. P. Ramsay, 1878, south-east coast of New Guinea. Forms a superspecies with *L. squamata*. Two subspecies recognized.
Subspecies and Distribution.
L. a. olivacea Mayr, 1938 – lowlands of NC New Guinea, from L Sentani and Idenburg–Mamberamo rivers E to Ramu R, including middle and lower Sepik R.
L. a. alboauricularis (E. P. Ramsay, 1878) – coastal lowlands of SE New Guinea E from Popondetta and, in S, from around Bereina to Milne Bay, including small coastal islands of Mailu (off Amazon Bay) and Heath and Doini (near Samarai I).
Descriptive notes. 15 cm; male 13.5–19 g, three females 12.5–14.5 g. Nominat race is dull brown above, darker olive-brown on wing and tail, with faint buff tips on median coverts, olive-green outer edges on outer greater coverts and remiges (diffuse greenish wash on folded wing), and with broad, diffuse olive-green outer edges on rectrices; in fresh plumage, edges of upperpart feathers faintly paler, giving slight mottled or streaked effect; broad but sparsely feathered dark brown to blackish-grey crescent from lower lores to beneath and behind eye, variably flecked with prominent (but sparse) small black feathers, this crescent bordered at rear edge by large pale patch on

ish-grey to dark brown; bill black-brown to black; legs grey to blue-grey. Sexes alike in plumage, male larger than female. Juvenile undescribed. Race *olivacea* is like nominate, but darker olive above. VOICE. Noisy. Main call, often given by several birds at same time, a loud descending series of musical but coarse, squawking notes, “skwitch-skwitch-skwitch...”, “kweek-kweek-kweek...”, “shree-shree-shree-shree...” or “szi-szi-szi-szi...”, usually of 5 notes and given rapidly; described also as loud descending series, accelerating towards end, “chip...chip-chip-chip-chip-chip-chip”. Reported also as giving variant that ascends in pitch and decelerates. Dawn call a repeated, lively, sibilant “jit”. Song described as coarse trill, this possibly same as one of aforementioned vocalizations; song also said to be identical to that of *L. indistincta*.

Habitat. Usually near water. Preferred habitat tall canegrass (*Saccharum*) and other grasses (e.g. *Imperata*), often in or bordering wetlands, but also inhabits canegrass savanna with scattered shrubs and trees, and commonly in mangroves. Found also in groves of coconut palms or *Pandanus* in or bordering canegrass or beside lagoons and other wetlands; reeds in riparian marshland; riparian secondary growth; riparian and coastal scrub; coconut plantations; and locally common in trees and shrubs in gardens of some towns or homesteads. Said to occur also in riparian woodland. Confined to lowlands, usually near coast.

Food and Feeding. Nectar and insects. Forages among stems and leaves of canegrass, and among other foliage; seen also to forage at flowers (including *Melaleuca*, coconut palms, and *Hibiscus* in gardens). Singly, in twos (probably pairs) or in small groups. Active, conspicuous and often confiding; moves rapidly in dense vegetation, and can be difficult to observe.

Breeding. Recorded in most months, with possible peak in late dry season (Sept–Oct) and little or no breeding in early wet season, clutches early Mar, Apr, Jun–Jul and Sept–Oct, active nests Aug and Nov, and juveniles Apr; also nest-building in Nov and Dec and birds in breeding condition late Mar to Apr. Nest built by both sexes, usually taking 7–10 days, sometimes only four days, a neat, compact but still fairly substantial cup of dead leaves, plant fibres (e.g. of coconut palm), small pieces of bark and some dried grass, bound with spider web and egg sacs and cobweb, lined with plant down, occasionally incorporating artificial materials (e.g. pieces of paper, and threads of plastic) when around human habitation, two nests externally 78 × 57 mm and 70 × 64 mm; usually suspended by rim from outer twigs, commonly in shrubs but also in trees (including coconut palm) or in herbs and suggested that probably mainly in canegrass, mean height above ground 1.7 m for 21 nests, of which 14 in shrub less than 2 m tall, five in raintree (*Samanea*) 2–5 m above ground, and singles 1.5 m up in yam (*Dioscorea variegata*) and 2.5 m above ground in mango (*Mangifera indica*). Clutch 2 eggs; incubation period for one egg 14 days; chicks fed by both parents, nestling period for one chick 12 days; parents did not abandon eggs or nestlings even when observed closely.

Movements. No information; probably largely resident.

Status and Conservation. Not globally threatened. Considered locally common to abundant; recently found to be uncommon in Idenburg–Mamberamo Basins. Unconfirmed reports of nominate race in Ok Tedi region (Ok Ma and Ok Menga), to 750 m; perhaps unlikely, but meriting investigation.

Bibliography. Anon. (1978b), Archbold *et al.* (1942), Beehler *et al.* (1986), Bell (1970a), Coates (1990), Coates & Peckover (2001), Eastwood (1989b), Finch (1980b, 1983), Gilliard & LeCroy (1966), Gregory (1995b, 1996), Hartert (1930), Heron (1974, 1977b), Hicks (1990a, 1990c), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Richards & Suryadi (2002), Schönwetter & Meise (1981), White & Bruce (1986).

134. Buru Honeyeater

Lichmera deningeri

French: Méliphage de Buru **German:** Buruhonigfresser **Spanish:** Mielero de Buru

Taxonomy. *Stigmatops deningeri* Stresemann, 1912, Buru, Moluccas.
Forms a superspecies, and possibly conspecific, with *L. monticola*. Monotypic.

Distribution. Buru, in S Moluccas.

age, female smaller and apparently slightly paler than male. Juvenile undescribed. VOICE. Song described as “kew-kew-kew”, rather like that of *Philemon* but softer.

Habitat. Primary rainforest, selectively logged and disturbed forest, tall secondary forest and scrub. Lowlands to 2060 m, mainly above 1500 m; in surveys in year 2000, recorded at 1240–1500 m.

Food and Feeding. No information on diet. Seen to forage at flowers of rhododendron and other plants. Seen singly and in twos (probably pairs); sometimes associates with *Myzomela wakoloensis* when foraging in same tree.

Breeding. A captive recently fledged juvenile in Nov to early Dec. No other information.

Movements. Presumably sedentary, with some local movement.

Status and Conservation. Not globally threatened. Restricted-range species: present in Buru EBA. Poorly known. No estimates of population, but described as generally uncommon.

Bibliography. Coates & Bishop (1997), Jepson (1993a), Jones *et al.* (1990), Poulsen & Lambert (2000), Siebers (1930), Stattersfield *et al.* (1998), Stresemann (1914b), White & Bruce (1986).

rear ear-coverts, silvery white on upper coverts and pale grey on lower ear-coverts; pale greyish-brown malar area becomes mottled with white on side of throat, merging into mottled brown-and-white side of neck; chin and throat off-white, speckled or diffusely streaked brown; underbody off-white, with pale yellowish wash on breast and even weaker tinge on flanks, and with brown streaking or even mottling heaviest across breast and upper belly, and largely petering out in centre of belly; undertail brown; underwing off-white, with brownish mottling on coverts, and with pale brownish-grey trailing edge and tip; iris brown-

135. Seram Honeyeater

Lichmera monticola

French: Méliphage de Céram **German:** Seramhonigfresser **Spanish:** Mielero de Seram
Other common names: Ceram (Mountain)/Moluccan/Spectacled Honeyeater

Taxonomy. *Stigmatops monticola* Stresemann, 1912, Seram, Moluccas.
Forms a superspecies, and possibly conspecific, with *L. deningeri*. Monotypic.

Distribution. W & C Seram, in S Moluccas.

Descriptive notes. c. 14.5–16.5 cm. Male is olive-grey above, paler greenish-olive on rump and uppertail-coverts, and diffusely streaked darker, dusky olive, on top of head, hindneck, side of neck, mantle, back and scapulars, some median and greater upperwing-coverts tipped yellowish-white; distinctive facial pattern of uniformly dark olive-grey forehead and lores, narrow grey to bluish-grey orbital ring bordered on lower half by partial eyering of small, stiff silvery white feathers, with narrow bare yellowish-buff line extending from yellowish gape beneath eyering and (at least sometimes) curving up a little behind it, greyish-white to yellowish-

white ear-coverts with small yellowish patch on uppermost rear coverts, long grey submoustachial stripe bordered anteriorly by fine pale malar line; greyish-white chin merging to dusky grey throat, mottled with white; underbody very pale greyish-yellow to pale olive-yellow, strongly streaked or mottled with dusky olive to grey-black on lower throat and breast, petering out on side of belly, and aligning to form long streaks on anterior underbody; centre of belly stronger yellow-olive to pale-yellow and unmarked; undertail brownish-grey; iris dark brownish-grey; bill black, yellow to yellowish-buff base of lower mandible and around nasal groove on upper mandible, and yellowish-buff gape; legs leaden grey or bluish-grey, with feet often dull brownish. Female is like male but smaller, also lacks white feathered eyering, this area instead bare. Juvenile undescribed. VOICE. Loud, repeated “tschök tschök tschök”, somewhat like alarm call of Common Blackbird (*Turdus merula*).

Habitat. Montane forest and, especially, montane heath at high altitudes, wherever main foodplants occur; on Mt Kobipoto, found in elfin moss forest above 2500 m. Recorded from 900 m to at least 2500 m, mainly above 1200 m; once down to 600 m.

Food and Feeding. Nectar and, presumably, insects. Main foodplants are ericaceous trees and shrubs, including *Rhododendron*, and seen to forage at flowers of these. Usually in small flocks.

Breeding. No information.

Movements. No information; presumed sedentary, probably with some local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA. Very poorly known. No estimates of population, but considered common to abundant. Absent from E of island, where altitude too low for this species.

Bibliography. Bowler & Taylor (1989a, 1993a, 1993b), Coates & Bishop (1997), Isherwood *et al.* (1998), Stattersfield *et al.* (1998), Stresemann (1914a), Verbelen (1996), White & Bruce (1986).

136. Yellow-eared Honeyeater

Lichmera flavicans

French: Méliphage de Timor **German:** Timorhonigfresser **Spanish:** Mielero de Timor
Other common names: Timor/Flame-eared Honeyeater

Taxonomy. *Melithreptus flavicans* Vieillot, 1817, “Nouvelle Hollande”; error = Timor.
May form a superspecies with *L. notabilis*. Monotypic.

Distribution. Timor, in E Lesser Sunda.

Descriptive notes. c. 12.5–14 cm. Distinctive, medium-small honeyeater with moderately long and sturdy decurved bill. Plumage is rich greenish-olive above, with blackish mask over lores, narrowly above and below eye and diffusely behind eye, bordered below by pale grey to pale bluish-grey submoustachial stripe and anterior ear-coverts, and with large, bold golden-yellow patch covering rear ear-coverts; mostly olive-yellow below, with dusky grey chin and upper throat merging to heavy but diffuse dusky olive spotting or streaking over lower throat, breast, upper belly and flanks; undertail greyish-olive; iris dark brown; bill

black; legs grey to blackish-grey. Sexes alike in plumage, male probably larger than female. Juvenile not fully described, like adult but lacks yellow ear-patch, and with less distinct spotting or streaking below. VOICE. Calls include varying series of short, rapid, bubbling whistled notes lasting c. 1.5 seconds; brief soft nasal “bzz” and louder variant of this, which possibly same as harsh “fssh” notes (also reported). Somewhat harsh chortling song, some notes with bell-like quality, and variety of other phrases including “ik-a-blik”, “ze-plerk” and “klook-klook”.

Habitat. Monsoon forest, forest edge, riparian woodland, secondary growth, and open forest of *Eucalyptus urophylla*. Lowlands (at least 230 m) to 2000 m, mainly 500–1000 m.

Food and Feeding. Diet includes nectar and insects. Apparently mainly nectarivorous, foraging at flowers mainly in upper middle storey. Seen singly and in twos (probably pairs).

Breeding. Single report of breeding in Apr. No other information.

Movements. Resident, probably with some local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Timor and Wetar EBA. No estimates of population level; considered common but patchily distributed.

Bibliography. Coates & Bishop (1997), Hellmayr (1914, 1916), Mayr (1944a), Noske (2003), Noske & Salch (1994, 1996, 1997), Stattersfield *et al.* (1998), White & Bruce (1986).

137. Black-necklaced Honeyeater

Lichmera notabilis

French: Méliphage de Wetar **German:** Finschhonigfresser **Spanish:** Mielero Acollarado

Other common names: Black-chested/Finsch's/Wetar/White-bellied Honeyeater

Taxonomy. *Stigmatops notabilis* Finsch, 1898, Wetar, Lesser Sunda Islands. May form a superspecies with *L. flavicans*. Monotypic.

Distribution. Wetar, in E Lesser Sundas.

across side of neck and across upper breast as bold narrow breastband, enclosing large white throat

Descriptive notes. c. 13–15 cm. Striking, medium-small honeyeater with moderately long, slender and gently decurved bill. Plumage is largely yellowish-olive above, with dull black forehead becoming boldly streaked blackish on hindneck, side of neck, and mantle, back and scapulars; distinctive facial pattern of narrow whitish supercilium extending behind eye over rear ear-coverts, dull black and sparsely feathered lores, blackish ear-coverts finely speckled with silvery grey feather tips (can appear pale silvery grey with black speckling), and strong black moustachial stripe continuing below rear ear-coverts and curving down

patch (covering malar area, chin and throat); underbody below breastband yellow, rear edge of breastband breaking into black streaking across rest of breast, upper belly and anterior flanks; iris dark brown to reddish-brown; bill black; legs grey to bluish-grey. Sexes alike in plumage, male probably larger than female. Juvenile undescribed. **VOICE.** No information.

Habitat. Lowland monsoon forest and gardens; observed also in mosaic of coastal scrub, overgrown cultivation and tall secondary woodland.

Food and Feeding. Forages at flowers in canopy and in tangles of vines; seen singly and in twos (probably pairs). No other information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Timor and Wetar EBA. Very poorly known. No estimates of total population, but considered generally uncommon within its tiny global range, which restricted to a very small island. Extensive forest remains on Wetar, including lowland and hill forests and savanna woodland with intrusions of semi-evergreen monsoon forest; logging of unknown extent is occurring, however, and loss of lowland habitats could have been substantial. Wetar also has a low human population, and there were plans for transmigration settlements from elsewhere in Indonesia, although these have apparently been set aside.

Bibliography. Anon. (2007c), Butchart & Stattersfield (2004), Coates & Bishop (1997), Collar *et al.* (2001), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), White & Bruce (1986).

138. Crescent Honeyeater

Phylidonyris pyrrhopterus

French: Méliphage à croissants **German:** Goldflügel-Honigfresser **Spanish:** Mielero Alafuego
Other common names: Crested/Egypt/Horseshoe/Tasmanian/Lesser Crescent Honeyeater

Taxonomy. *Certhia pyrrhoptera* Latham, 1801, Nova Hollandia = region of Port Jackson, New South Wales, Australia.

Proposed race *indistinctus* (from Mt Lofty, in S Australia) is considered inadequately differentiated from *halmaturinus*, and *rex* (from King I. in Bass Strait) and *inornatus* (Tasmania) are synonymized with nominate. Two subspecies recognized.

Subspecies and Distribution.

P. p. halmaturinus (A. G. Campbell, 1906) – Mt Lofty Ranges S to Fleurieu Peninsula and on Kangaroo I, in SE South Australia.

P. p. pyrrhopterus (Latham, 1801) – SE Australia on and E & S of Great Divide, from CE New South Wales (S from about Gosford, inland to Bathurst) S to E & S Victoria and extreme SE South Australia; islands in Bass Strait (King I, Kent Group, Furneaux Group); and Tasmania (including offshore islands).

Descriptive notes. 14–17 cm; male 15–23 g and female 12–20 g (nominate), male average 15.2 g and female average 12.5 g (*halmaturinus*). Male nominate race has head, neck and upperbody dark grey, faint paler grey streaking on top of head and neck and side of neck, with grey-black forehead, narrow white supercilium bordered below by diffuse black eyestripe to behind eye, and white malar area, chin and throat heavily but finely streaked dark brown; uppertail black, bold golden-yellow panel on basal side, white tips on inner webs of outer rectrices (usually seen only when tail spread); upperwing black, fine pale tips on tertials, bold yellow edges on other remiges (striking golden-yellow panel on folded wing); underbody largely brownish-grey, white breast marked with bold narrow black crescents extending toward mid-line; undertail grey-brown, off-white tips on outer feathers, underwing light grey-brown; iris dark red; bill and gape black; legs dark grey. Female is like a smaller, duller and washed-out version of male: upperparts mainly dark olive-brown, merging to lighter brown on rump and uppertail-coverts, head with reduced and dull, buff rear supercilium, indistinct dusky eyestripe, yellow panels on upperwing and tail much

duller, yellow-olive; brownish-grey of lower underbody merges to off-white on breast, where dark crescents much duller olive-brown, and lower breast streaked brownish-grey, also lacks obvious white tips on outer rectrices. Juvenile male is like adult female, differing mainly in mostly creamy breast lacking crescents (at most, some dark feathers at side of breast), darker black-brown eyestripe, wing and tail much as in adult male (bright yellow panel on folded wing much brighter than that of female) and prominent white tips on rectrices, off-white to yellow gape, and dull dark-brown iris; juvenile female similar to juvenile male, but eyestripe, wing and tail like those of adult female, from which differs in juvenile pattern of breast. Race *halmaturinus* is significantly smaller than nominate but with significantly longer bill, slightly shorter and less distinct supercilium, slightly duller yellow on wing and tail, and slightly shorter white tips on rectrices, adult female further differs from female nominate in less distinct breast-crescents. **VOICE.** Noisy, with varied and complex repertoire of contact and social vocalizations; throughout year, and at any time of day, from or before dawn, but most often in breeding season; sometimes utters same vocalization repeatedly for several minutes, whereas at other times bouts made up of several different vocalizations. Male louder than female. Main calls a loud, high-pitched “eejik” or “e-gypt”, stress on second syllable, and a simple sharp “jik”, like second note of “eejik”; “eejik” said to be usual in spring and summer, and “jik” in winter. In alarm a harsh, broad-frequency chattering (probably equivalent of harsh scolding given when threatened) and narrow-frequency tonal whistles; when mobbing, alternates between chatter and whistle. Male also has complex melodious song, from exposed or concealed perch; occasionally continuous piping in song flight while quivering wings. Both members of pair heard to utter a series of soft low notes when female on nest and male nearby. Calls of two or more syllables given significantly more often by male during breeding season than in non-breeding season; monosyllabic calls by male throughout year, possibly to maintain contact with mate. Male usually calls from same perches for some months, and calls more than female; in 66% of observations males were calling loudly and in 8% softly, whereas females called softly in 8% of sightings and were silent in rest. Can snap bill in aggression.

Habitat. Often found in tall, *Eucalyptus*-dominated sclerophyll forests, including wet sclerophyll forest, typically with well-developed middle storey of *Acacia* or understorey of tall dense shrubs;

and open and drier eucalypt forests with well-developed understorey, especially gully associations with dense shrub layer and ground cover. In Tasmania, occurs equally commonly in dry and wet sclerophyll forests. Also frequently present in eucalypt woodlands with dense heath shrub layer or understorey of heath; in Mt Lofty Ranges to Fleurieu Peninsula (race *halmaturinus*), inhabits open stringybark eucalypt forest with heath understorey that grades to open shrub and heath on steeper slopes. At higher altitudes, commonly in subalpine forest or woodland dominated by eucalypts, especially snow gums (*Eucalyptus pauciflora*), or conifers, often stunted, and with dense and floristically rich shrub layer. Less often in closed eucalypt-beech (*Eucalyptus-Nothofagus*) forest with dense understorey of ferns, or in low closed forest dominated by lilly pilly (*Acmena smithii*); very occasionally in mallee eucalypt woodland, though more often in mallee heathland. In coastal regions, often in dense heathland or shrubland dominated by vegetation such as tea-trees (*Leptospermum*), paperbarks (*Melaleuca*), *Banksia* and Epacridaceae; at higher altitude, in alpine heathland, scrub or moorland. Also in heath-woodland with dense shrub layer, such as *Banksia* woodland. Occasionally in sedge-lands. Sometimes found in urban parks and gardens; and pine plantations.

Food and Feeding. Nectar, fruit and insects, as well as manna, honeydew and lerp. Near Adelaide (South Australia), fed on nectar and insects in roughly equal proportions. Forages mostly in shrubs of understorey or in middle storey, also in canopy of tall forest or woodland and very occasionally on ground; mean foraging height at one site 4.7 m, with 74% of 177 feeding observations in shrubs. Searches at flowers, among foliage, on bark of trunks and branches, and occasionally in air or on ground. Mainly probes (for nectar at flowers, and for insects on loose bark and trunks of trees and shrubs) and gleans (foliage, branches and loose bark); less often sallies, including sally-strikes at prey on foliage, and sallying in air. When feeding on nectar of *Banksia ericifolia*, spent mean of 15.3 seconds per visit (range c. 10–60 seconds); when feeding on *Astroloma conostephioides* and *Eucalyptus cosmophylla*, visited respectively 34 and 31 flowers per minute. In pairs; in non-breeding season also in small loose parties, and may congregate in larger numbers (15–20 individuals) at sources of abundant food; some move in loose feeding flocks.

Breeding. Recorded in all months except Jun, mainly late winter and spring, nominate race eggs Jul–Jan and nestlings late Jul and Sept–Mar, *halmaturinus* eggs Jul–Oct, Dec and Feb–May and nestlings Nov and Apr (Mt Lofty Ranges) and eggs Jul–Aug and Oct and nestlings Oct (Kangaroo I); in one season in S Victoria, pairs made mean of 2.86 nesting attempts per season, but only one pair successfully raised two broods. Breeds in simple territorial pair or in semi-colonial cluster. Nest built by female, a bulky untidy cup of strips of bark, grass, twigs, rootlets, leaves and other fine plant fibres, some lightly bound with spider web, lined with soft grass, bark, plant down, moss, fur, hair, feathers, exterior can have small clumps of moss attached, 49 nests from S Victoria had mean external diameter 132 mm, depth 88.5 mm, internal diameter 51.5 mm, depth 46 mm; usually supported, but sometimes suspended by rim or sides, in upright or horizontal fork, among dense foliage of low shrub or other vegetation, including low ferns such as bracken (*Pteridium esculentum*) or clump of sword-grass (*Gahnia*), 0.25–3 m (mean 1.26 m) above ground throughout range (almost identical heights in S Victoria alone, mean 1.27 m), typically near centre of nest plant and often sheltered from above; site often in dense understorey near creek in gully. Clutch usually 2 eggs, occasionally 1 or 3, mean throughout range 2.06 (mean in S Victoria 2.82), claims of occasional 4-egg clutches require confirmation; incubation by female, begins with laying of second egg, period in S Victoria 13.1–13.5 days (mean 13.2 days); chicks brooded by female, fed by both sexes, female providing almost twice as many feeds as male, nestling period 13 days, young leave nest prematurely at 12 days if disturbed; fledglings fed and tended by both parents, feed independently after 10–28 days; male may undertake most or all care of fledglings if female renests. From 17 eggs in seven nests, 0.57 fledged young per nest; from 76 eggs in 27 nests in S Victoria during one season, success 0.82 young per nest, and 29.6% of nests fledged at least one young.

Movements. Resident over most of range, some altitudinal migration in parts of range in Tasmania and SE mainland. In Southern Highlands of Australian Capital Territory–SE New South Wales, present at higher altitudes and virtually absent at lower altitudes during spring–summer, but numbers at higher altitudes decline and birds commonly recorded at lower altitudes (in Canberra and on coast) during winter; largely resident in coastal and subcoastal E Victoria, with numbers augmented in winter by apparent migrants from highlands. In Tasmania, mainly autumn–winter visitor to lowlands and coast, only few remaining at low altitudes in spring–summer. Some seasonal movements local, e.g. at Toolangi, in S Victoria, present throughout year but moves out of gulleys in winter. Also, irregular visitor at some sites, and described as nomadic or partly nomadic; some movements said to be related to exploitation of nectar sources. Influxes occasionally recorded. Sometimes seen far from normal range.

Status and Conservation. Not globally threatened. Locally common. No estimates of total population; recorded densities of 0.06–8.7 pairs/ha at various sites. Widespread in Tasmania, but sparsely scattered in NE & SW.

139. New Holland Honeyeater

Phylidonyris novaehollandiae

French: Méléphage de Nouvelle-Hollande **Spanish:** Mielero de Nueva Holanda

German: Weißbaugen-Honigfresser

Other common names: Yellow-winged/White-bearded/Bearded/Golden-winged/Long-billed/White-eyed Honeyeater

Taxonomy. *Certhia novaeHollandiae* Latham, 1790, “Nova Hollandia” = region of Port Jackson, New South Wales, Australia. Five subspecies recognized.

Subspecies and Distribution.

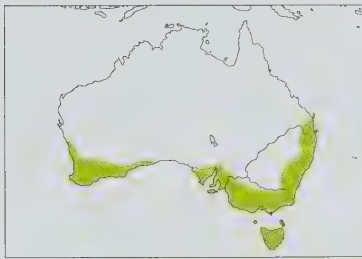

P. n. longirostris (Gould, 1846) – SW & S Western Australia S & SE from about Geraldton (occasionally farther N) to Esperance, thence coastally and subcoastally to Israelite Bay.

P. n. novaehollandiae (Latham, 1790) – SE mainland Australia from SE Queensland (S from Gympie) and E New South Wales (reaching W slopes of Great Divide) S to S Victoria (extending farther inland in W) and SE South Australia (E from Eyre Peninsula).

P. n. campbelli (Mathews, 1923) – Kangaroo I (South Australia).

P. n. caudatus Salomonsen, 1966 – King I and Furneaux Group, in Bass Strait.

P. n. canescens (Latham, 1790) – Tasmania.

Descriptive notes. 18 cm (16–20); male 10–25 g and female 10–23 g (nominate), male 13–23 g and female 10.5–20 g (*longirostris*), male 20.5–22 g and female 18–19 g (*campbelli*), male 22.3–29 g and female 19.8–23 g (*caudatus*), male 20–24 g and female 16.5–23.5 g (*canescens*). Striking medium-sized honeyeater, strongly black and white and with distinctive head pattern, conspicuous pale eye. Nominate race has head mainly black, with small white-streaked patch at side of forehead, white lateral crownstripe, broad wispy white malar plume, prominent white neck plume (below and behind ear-coverts and fanning onto

side of neck), and elongated white bristles on lower throat (appearing as finely streaked beard); upperbody mostly black-brown, with diffuse grey-brown streaking on neck, bold white streaking on mantle and scapulars, and fine brown streaking on back, rump and uppertail-coverts; upperside and uppertail brownish-black to black, remiges and rectrices with bright yellow outer edges (striking panels on folded wing and side of tail), small white tip on outer tail (when tail spread, white tips visible on all except central feathers); underparts white, boldly streaked with black, undertail greyish-brown with broad off-white tip, underwing greyish-brown with paler leading edge of coverts; iris white; bill and gape black; legs blackish-brown. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult but much duller and paler, head and neck dark brown with yellow tinge in white markings (other than neck plume), upperparts brown with faint grey-brown streaking, underparts off-white and more sparsely streaked with dark brown, upperside with paler brown fringes on greater coverts, yellowish edges on greater primary coverts, paler yellow panel on folded wing, iris dark grey or grey-brown, bill black-brown or grey-brown with pale tip and base, gape pale yellow and swollen, legs tinged pink. Races differ in morphometrics and slightly in plumage: *longirostris* is like nominate in size but with longer bill, much smaller and narrower malar plume; *campbelli* is on average larger than nominate, with significantly shorter wing and longer bill than adjacent mainland populations, has sparser white beard, blacker mantle and back with finer white streaking, black streaking on breast broader; *caudatus* male is significantly larger than male nominate, female similar in size to female nominate but significantly longer-tailed, both sexes with plumage very like previous but with longer malar plume; *canescens* is similar in size to nominate but female significantly longer-tailed, differs from nominate in slightly longer white malar plume, sparser white beard, and slightly broader black streaking on breast. VOICE. Noisy, with complex repertoire dominated by simple single-note calls. Probable contact or location calls given regularly, consist of high-pitched single or double note, e.g. “cheet”, “seet”, “sssee” or “sit”. Alarm calls in response to predators a rapid series of loud penetrating descending staccato whistled notes (audible to 500 m) and a chatter of short harsh notes usually in short series (audible only to 20–30 m), may alternate between these when alarmed; staccato whistles from high exposed perch, then while diving to cover as predator nears, the usual alarm in response to raptor; chatter also from high perch or from dense shrub in response to approach of other type of predator or potential threat; chatter may be given also during distraction display. Corroborate call a repeated single note, given only during corroborees (see page 534). Male has soft, warbling flight song, roughly rendered as 2–6 repeated “yeeep” calls, uttered during last half of outward song flight and apparently adjusted to length of song flight; occasionally given when perched. Other calls include “squark”, during intraspecific chases; a series of 2-note whistles, given from high exposed perch for up to two minutes at a time, function of which not known; and harsh distress call or rapidly repeated “chirrup” that may be given during fighting. Snaps bills during chases and nest defence.

Habitat. Mainly heathland and dense shrubland, including mallee heathland, sometimes with scattered emergent *Eucalyptus* or *Angophora*, and consisting of diverse range of shrubs such as *Banksia*, *Leptospermum*, *Melaleuca*, casuarinas, epacids, and other proteaceous or myrtaceous shrubs. In Tasmania, also in buttongrass (*Gymnoschoenus sphaerocephalus*) sedge-land. Also in eucalypt woodland or dry, open eucalypt forest with dense shrub or heath understorey; occasionally in mallee woodland or shrubland, sometimes with broombush (*Melaleuca uncinata*) in understorey. In SW Australia, recorded in jarrah (*Eucalyptus marginata*) forest with middle storey including *Banksia grandis* and a low shrub layer. Occasionally in wet sclerophyll forest, usually with well-developed understorey, in E Australia. Sometimes in pine plantations near eucalypt forest, or edge of closed forest. Often in parks and gardens in urban areas.

Food and Feeding. Mainly nectar, also manna, and arthropods, lerp and honeydew (of eriococcids and psyllids). Arthropods mainly insects and their larvae, but also mites and ticks (Acarina) and spiders (Araneae). Tends to feed mainly or almost exclusively on nectar, but in a few studies diet found to comprise higher proportion of insects than of nectar; foraging behaviour varies with season and time of day (e.g. breeding birds usually take more insects). Time spent in foraging may vary with changes in availability of nectar; most of the time spent in foraging when nectar scarce, but little time in foraging when nectar abundant. Forages mainly in shrub layer, but also at all levels from canopy to, rarely, ground. Nectar obtained by probing flowers; insects taken mainly by sallying (including sally-striking for flying insects, and sally-hovering) and by gleaning from foliage or bark of branches and trunks; other carbohydrates obtained by gleaning and probing. Forages singly, in pairs or in small groups. Singletons or (especially when breeding) pairs defend feeding territory, either throughout year (but with variation in intensity and duration of defence) or only for short periods, by attacking and chasing intruders, also displacing other birds, and occasionally fighting; small groups also seen to defend territory; territorial behaviour and social organization vary with abundance of conspecifics and other nectarivores in avian community (e.g. small honeyeaters usually readily driven off, but larger *Anthochaera* wattletbirds and *Glossopsitta lorikeets* difficult to evict), vary also with number of intrusions, and with abundance and density of resources, e.g. in S Australia up to 20 of present species (and occasionally *Anthochaera carunculata*) defended individual feeding territories in single tree. Occasional

anecdotal observations of birds congregating in an area to forage on abundant resources (but individuals may still defend territories).

Breeding. Recorded throughout year but season mainly winter–spring, with 55% of clutches Aug–Oct and 71% Jul–Nov, and only 6% Dec–Feb; at one site in New South Wales season centred on winter peak of nectar availability, laying beginning mid-Feb (when nectar availability low) and most pairs nesting late Feb/Mar to mid-Aug; in Victoria two distinct breeding periods at one site, with eggs in spring (Jul–Oct) and autumn (Feb–Apr), but at a second site clutches recorded only in spring (Aug–Oct). Occasional instances of co-operative breeding, with helpers. Nest built by female, often accompanied by male, usually a neatly woven cup typically made of grass, strips of bark, twigs, leaves (including casuarina and pine needles), rootlets, pieces of vine, and cobweb and wool, lined with fine grasses and plant down (e.g. from *Banksia* inflorescences, *Macrozamia* cycads, or ferns), flowers or floral parts (e.g. *Banksia* bracts), moss, soft seeds, or wool, fur, hair or feathers, external diameter 7.6–12 cm, depth 6.4–8.9 cm, internal diameter 5.1–5.7 cm, depth 3–3.8 cm; nests in Victoria had three distinct layers, outer layer of dead twigs, usually bound with spider web, middle layer of strips of bark or vines and some bark, and lining of soft plant material and wool (extending c. 1 cm up sides of nest); either supported in upright fork or suspended by rim, and usually well concealed in foliage of live shrub or small tree, less often in ferns, rushes or grass or other low sites, 0.05–7 m (mean 1.33 m) above ground. Clutch usually 2–3 eggs, occasionally 1 (few records of 4, but not certainly laid by only one female), mean for whole range 2.09, in E appears to increase with increasing latitude (New South Wales 2.05, Victoria 2.19, South Australia 2.13, Tasmania, 2.38), mean in Western Australia 2.11; incubation by female, usually from completion of clutch, period 13–15 days; chicks brooded by female, fed by both sexes (female providing more feeds), occasionally assisted by helpers, nestling period 12–16.5 days, young sometimes leave nest prematurely if disturbed; fledglings tended by both parents, occasionally also by helpers, at two sites in Victoria young independent c. 4 weeks after fledging. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*) and Horsfield’s Bronze-cuckoo (*Chrysococcyx basalis*). From 490 eggs in 243 nests for which outcome known, 0.56 fledged young per nest; of 327 nests, 67% fledged at least one young; predation a major cause of failure, known predators of eggs or young include Laughing Kookaburra (*Dacelo novaeguineae*), Pied Currawong (*Strepera graculina*), Spotted Harrier (*Circus assimilis*) and black rat (*Rattus rattus*), and snakes also thought responsible for much predation.

Movements. Primarily resident; some movements, probably largely local. Descriptions as nomadic, partly nomadic and locally nomadic often based solely on irregular or apparently unpredictable occurrence at sites. Suggested that probably permanently resident where nectar available throughout year, and undertaking local, sometimes seasonal, movements elsewhere. Such movements can result in influxes at sites where nectar available, and thus increases in numbers in areas where resident populations occur. Where flowering seasonal, movements and occurrence may also be seasonal. Occasional visitor at some sites, and vagrants recorded well beyond normal range. At any given site, mobile population typically transient, with few retraps of ringed individuals; in one study also found that most (69%) were immature. Sometimes observed while moving in flocks on apparent passage, sometimes with *Lichenostomus chrysops*. An influx S of Sydney coincided with irruption of *P. niger*.

Status and Conservation. Not globally threatened. Locally common. Widespread in SW and in much of SE, widespread also in Tasmania; more sparse in N of range and in W part of South Australian range (only scattered records on Eyre Peninsula). No estimates of total population, but many estimates of density from throughout range; maximum recorded densities 20 birds/ha and c. 38 birds/ha, and of 16 breeding birds/ha. Range has possibly expanded on Adelaide Plain, in South Australia, where said to have become established since mid-1970s.

140. White-cheeked Honeyeater

Phylidonyris niger

French: Méliphage fardé **German:** Weißohr-Honigfresser **Spanish:** Mielero Cariblanco
Other common names: Herberton/Moustached Honeyeater

Taxonomy. *Certhia nigra* Bechstein, 1811, “Neuholland” = region of Sydney, New South Wales, Australia.

Two subspecies recognized.

Subspecies and Distribution.

P. n. gouldii (Schlegel, 1872) – coastal and subcoastal SW Australia from Murchison R S to Esperance–Israelite Bay, occasionally E to Eyre Bird Observatory (50 km S of Cocklebeiddy).

P. n. niger (Bechstein, 1811) – E Australia on and E of Great Divide, from NE Queensland (Mt Windsor Tableland S, inland to Wongabel, Ravenshoe and upper reaches of Burdekin R, to Paluma Range) and, disjunctly, from Eungella National Park (inland from Mackay) S to SE New South Wales (Illawarra region to Shoalhaven R).

Descriptive notes. 16–20 cm; male 15.5–25 g and female 15.5–20.5 g (nominate), two males 18.1 g and 21.5 g and one female 16 g (*gouldii*). Striking, medium-sized honeyeater with strongly pied appearance. Nominate race has head and neck mostly black, small white patch at side of forehead meeting narrow white lateral crownstripe, and with broad triangular white cheek patch fanning out to cover ear-coverts, and sides of neck and throat; upperparts largely black-brown, heavily streaked white from nape to mantle, back and scapulars, mottled brown on rump and uppertail-coverts; diffuse black-brown mottling on black upperswings-coverts and alula, bright golden-yellow outer edges of remiges (conspicuous panel on folded wing); uppertail brown, bold golden-yellow panel at side; chin to throat black, underparts largely white, with black streaking heavy on breast, very sparse in centre of belly and merging to black-brown mottling on undertail-coverts; flanks and thighs brownish; underwing off-white to pale greyish-brown with broad dark brown

wispy and differently shaped white cheek patch narrowing towards rear. Voice. Noisy, with frequent loud chattering. Four main call types recognized. Variety of brief calls, typically of 1–3 notes, with loud 2-note “e-chip” common and characteristic. Other brief calls include short “tu-tu” (may be an appeasement signal), loud clear double whistle, often repeated rapidly several times in succession, and squeaky single-note whistle. Corroboree call (see page 534) a series of single-note calls. Alarm in response to predator includes continuous rasping and a rapid “hee-hee-hee...” call. Male song a melodious warbling “twee-ee-twee-ee”, preceded and followed by a few chirps and whistles, given during song flights and occasionally when perched. Snaps bill during chases.

Habitat. Primarily low moist to wet heathland or, less often, drier heathland, or ecotone between dry and wet heathland, sometimes with taller emergents. Often low shrubland or other dense vegetation, especially in damp or swampy areas, such as swamps of bottlebrush (*Callistemon*), paperbark (*Melaleuca*) and tea-tree (*Leptospermum*) or riparian associations. Heathland and shrubland typically include *Banksia* species, as well as *Melaleuca*, *Acacia*, *Calothamnus* and *Adenanthos*; in SW Australia, some apparent preference for *Dryandra*, which usually present in occupied habitats. Occurs in some areas in moist sedgeland with patches of, or scattered, flowering shrubs (e.g. *Baeckea*, *Grevillea*), and sword-grass (*Gahnia*) swamps. Commonly in woodlands dominated by *Eucalyptus*, *Angophora* or *Banksia* and with dense shrub or heath understorey; less often in open forest with open shrubby understorey, and only occasionally in wet sclerophyll forest; in SW, very occasionally in open forest dominated by jarrah (*Eucalyptus marginata*), marri (*Eucalyptus calophylla*) or wandoo (*Eucalyptus wandoo*). In NE Queensland, mainly in wet sclerophyll or tall open eucalypt forest, often along watercourses, and in riparian woodland or thickets of *Callistemon*; sometimes at rainforest edge. Occurs in parks and gardens and along streets of urban areas throughout range.

Food and Feeding. Mainly nectar, also insects. Frequently takes nectar from *Banksia* and *Eucalyptus*, and, in SW Australia, *Dryandra*, but also from wide range of other rich nectar-producing Proteaceae, Myrtaceae and Epacridaceae, including *Grevillea*, *Lambertia*, *Darwinia*, *Adenanthos*, *Calothamnus* and *Epacris*. Proportions of food types in diet vary greatly, reflecting seasonal availability of food resources and breeding requirements, e.g. in one study in CE Australia 96.7% of time spent in feeding on two species of *Banksia*, whereas in another study in same area 78% of observations involved insect-catching; at one site in SW Australia, ratio of nectar to insects in diet 72:28. Time spent in foraging correlated with changes in availability of nectar; at one site, foraging comprised 14% of observations in one year and 7% in another. Arboreal, foraging at all levels from low shrubs to canopy and aerially above canopy, but usually at low levels, typically in shrubs; only occasionally feeds on or from ground. Probes flowers for nectar. Frequently sallies for aerial insects, including sally-striking and sally-hovering, and can catch several insects in single flight; also gleans insects from foliage and bark. Active, noisy and conspicuous. Singly, in twos and often in small groups of up to 10–20 individuals, occasionally in larger assemblages; gregariousness appears to vary, possibly reflecting abundance of resources and season, e.g. at one site often foraged in groups in both breeding and non-breeding seasons, but at another site flocks not observed.

Breeding. Recorded in all months, with peak in winter, eggs or estimated laying Feb–Dec (mainly Apr–Aug); in New South Wales 80% of clutches Apr–Aug (peak in Jul), in W Australia 76.2% of 21 clutches in Jun–Aug; in Brisbane Water National Park (New South Wales), nesting usually centred around winter flowering of heath banksia (*Banksia ericifolia*), with 1–4 clutches per territorial male per year. Nest built by female alone, cup-shaped, often with flattened rim, made of fine twigs, strips of bark, plant stems, grass, spider web and, sometimes, wool, lined with fine grass, casuarina needles, spider web and floral parts or small flowers or seedheads and plant down, external diameter 8.3–11.4 cm, depth 7–7.6 cm, internal diameter 4.4–5.1 cm, depth 3.5–3.8 cm; suspended by rim and typically well concealed in lower branches of shrub or small tree (often in upright fork) or in grasses, generally 0.15–3.6 m (mean 0.58 m) above ground, 96% of nests below 1 m, mean height of nest plant 1.1 m; sometimes resting on ground, and occasionally as high as 6.1 m; in Brisbane Water National Park builds in clumps of vegetation higher and denser than surrounding heath, and near high point on which birds perch. Clutch 1–3 eggs, usually 2 (mean in W of range 2.12, in E 1.99); incubation by female, apparently from completion of clutch, period 13–15 days, possibly 15.5 days; chicks brooded by female, fed by both sexes, nestling period, 13–15 days, possibly up to 16.5 days, young leave nest early if threatened; fledglings fed by both parents, for up to several weeks, family ranging over 1–4 ha in first two weeks. From 119 eggs in 60 nests at which outcome known, average of 1.0 young fledged per nest. In SW Australia, estimated survival rates of adults and immatures combined 65.5%, and of juveniles 52%.

Movements. Apparently largely resident, with at least some movements; occurrence or changes in numbers often coincide with flowering of shrubs or trees, and considered seasonal or irregular visitor to some sites. Described as nomadic or partly nomadic by some authors, but most movements, where studied, are local, to exploit flowering in different habitats. Recorded all seasons at Wongamine Nature Reserve (SW Australia), but highest densities spring–summer and thought to be result of local populations congregating in response to flowering, rather than any movement into area. Predictable annual fluctuations in flowering may lead to seasonal patterns of abundance, e.g. study in in SW Australia found regular seasonal movements of up to 14 km within and between patches of remnant vegetation, main movements in late spring–early summer and autumn coinciding with flowering in different habitats at different sites; and in another study movements of up to 5 km recorded, again coinciding with seasonal flowering in different habitats and sites. Extent of some movements not known, e.g. in studies in Brisbane Water National Park (E Australia) present all year, but at times much movement through area, mostly by subadults, which usually remain for only few days. Influxes occasionally recorded, e.g. irruption of 200–300 individuals recorded around Nowra, in SE New South Wales, in late 1980. Vagrants occasionally farther inland, and in E of range farther S, into E Victoria.

Status and Conservation. Not globally threatened. Locally common; sparsely distributed in extreme SW. No estimates of global abundance, but recorded densities of 0.06–0.4 birds/ha.

Genus *TRICHODERE* North, 1912

141. White-streaked Honeyeater

Trichodere cockerelli

French: Méliphage de Cockerell **German:** Uferhonigfresser **Spanish:** Mielero de Cockerell
Other common names: Brush-throated/Cockerell's Honeyeater

Taxonomy. *Ptilotis cockerelli* Gould, 1869, Cape York, north Queensland, Australia. Genus formerly subsumed in *Lichmera*, or even in *Meliphaga*. Some similarities with *Phylidonyris*. Monotypic.
Distribution. NE Queensland (Cape York Peninsula S to Aurukun in W, and in E extending farther S along coast to Cooktown and Shiptions Flat), in NE Australia,

Descriptive notes. 14–17 cm; male 14–20 g, female 12–13.5 g. Has top and side of head grey, heavily speckled paler grey on lores, around eye and on anterior ear-coverts, with prominent bright yellow tuft on rear ear-coverts, and short bright yellow moustachial stripe extending back from patch of bright blue-grey skin at gape; gorget of lanceolate feathers on chin, throat and upper breast largely white, finely streaked grey-brown, more broadly on breast; hindneck, side of neck and upperbody dark brown, diffusely streaked black; uppertail black-brown with fine olive-yellow edges; upperwing largely black-brown, short white

wingbar across tips of median secondary coverts, bold greenish-yellow edges and whitish tips on greater coverts, narrow greenish-yellow fringes on tertials and broad greenish-yellow edges on secondaries and primaries (prominent panel on folded wing); underbody below gorget white, some bright yellow streaks at side of upper breast, and scattered brown spots and streaks on lower breast grading to more diffuse brown streaking on flanks and undertail-coverts; undertail dark grey; underwing pink-buff, merging to dark grey trailing edge and tip; iris red-brown, orbital ring light grey; bill black, pale blue-grey base and gape; legs blue-grey. Sexes alike. Juvenile is like adult but ear-tuft smaller, moustachial stripe reduced to a few yellow streaks, lacks obvious gorget (feathers not lanceolate), chin to upper breast appear pale yellowish with brownish streaking, upperparts warmer brown and only faintly streaked, upperwing browner, reduced median wingbar but contrastingly blackish primary coverts, underbody duller, off-white (yellow wash on some) and less coarsely and more sparsely marked, iris dark brown, orbital ring dark grey, bill dark grey with pale grey base but pale grey to cream gape, and legs darker grey; immature like adult but gorget pale yellow (not white), and retains some brownish juvenile plumage in upperbody and upperwing-coverts. **VOICE.** Calls loud. Main call said to be a series of rapid staccato notes or a rattle (like sound of machine-gun); also utters loud scolding notes or a metallic scolding "churr". Song a clear, sharp whistle or a liquid, high-pitched somewhat metallic whistle of 4 notes, "blink-blink-blink-blink". Other calls include drumming noise like sound made by string being twanged on wooden box.

Habitat. Mainly tropical dry open forests and woodlands dominated by eucalypts, sometimes mixed with paperbarks (*Melaleuca*), *Lophostemon* or *Banksia*, and with understorey varying from open and grassy to dense and shrubby; also tropical heathland, e.g. of tropical *banksia* (*Banksia dentata*). Sometimes found in paperbark woodlands, including swamp-woodland; occasionally in or at edges of rainforest or mangroves. From riparian flats and coastal foredunes to slopes and escarpments of sandstone ranges.

Food and Feeding. Mainly nectar; also arthropods (insects). Forages in crowns of low flowering trees or in shrubs (including *Eucalyptus*, *Melaleuca*, *Lophostemon suaveolens*, *Banksia*, *Grevillea*), among foliage and branches; sometimes in flowering mistletoes (*Loranthaceae*). Nectar taken directly from flowers, as are some small insects, by probing and gleaning; occasional sallies for flying insects. Seen to forage with many other species, mainly other honeyeaters (of at least six species), also with Olive-backed Sunbirds (*Cinnyris jugularis*).

Breeding. Not well known. Breeding recorded in wet season, with eggs in Jan and fledglings Jan and Apr, and in dry season, with unspecified breeding Apr–Jun, possibly Jul; may nest at any time when conditions suitable. Possibly nests in small groups, e.g. of 3–4 or up to ten active nests, timing possibly synchronous within groups. Nest a frail, deep and rather open cup made of interwoven fine grass, rootlets or plant fibres, bound with spider web, lined with fine grass, one nest had external diameter 7 cm, depth 7.6 cm, internal diameter 3.8 cm, depth 5.1 cm; either suspended by rim or supported on horizontal, terminal branchlets or, less often, in fork, usually poorly concealed, 0.45–2 m (mean 0.76 m) above ground in low open shrub or tree, once in tangle of vines running over ground; often at edge of swamp or bank of watercourse, sometimes above water. Clutch said to be always 2 eggs, but no quantitative data; no information on incubation and nestling periods.

Movements. Apparently resident, with local movements (described as locally nomadic), probably in response to flowering of trees; thought to move locally between forests and adjacent clearings. Vagrants occasionally recorded W of main range in S.

Status and Conservation. Not globally threatened. Restricted-range species: present in Cape York EBA. Fairly common; no measures of abundance.

Bibliography. Barrett *et al.* (2003), Beruldsen (1979, 1990), Beruldsen & Uhlenhuth (1995), Blakers *et al.* (1984), Forshaw & Muller (1978), Gannon (1962), Garnett & Crowley (1997), Higgins *et al.* (2001), Johnson & Hooper (1973), MacGillivray (1912, 1914, 1917, 1918), McLean (1995), Officer (1967), Pizzey (1980), Pizzey & Knight (1997), Schodde & Mason (1999), Stattersfield *et al.* (1998), Storr (1984), White (1922).

Genus *FOULEHAIO* Reichenbach, 1852

142. Wattled Honeyeater

Foulehaio carunculatus

French: Méliphage foulehaio **German:** Schuppenkopf-Honigfresser **Spanish:** Mielero Foulehaio
Other common names: Carunculated/Samoan Wattled Honeyeater; Viti Levu Wattled Honeyeater (*procerior*)

Taxonomy. *Certhia carunculata* J. F. Gmelin, 1788, Tongatapu, Tonga. Three subspecies recognized.

Subspecies and Distribution.

F. c. carunculatus (J. F. Gmelin, 1788) – Wallis and Futuna Is; E Fiji (Lau Group); Samoa (Savai'i, Upolu and offshore islets, including Nu'utele, Namua, Fanuatapu, Manono and Apolima); American Samoa (Tutuila and associated islets, and Manua Is); and Tonga (Vava'u Group, Ha'apai Group and Tongatapu Group).

F. c. taviunensis (Wiglesworth, 1891) – Vanua Levu, Taveuni and associated islets (including Mathuata, Nggamea, Rambi and Yangganga), in NC Fiji.

F. c. procerior (Finsch & Hartlaub, 1867) – W & C Fiji: Yasawa and Mamanuca Groups, Viti Levu, Vatulele, Beqa, Lomaiviti Group (including Ovalau), and Yasayasa Moala Group.

Descriptive notes. 19–21 cm; male 34 g and female 28 g (nominate), 25.2–45.4 g (*procerior*). Nominata race is largely drab to dark olive above, diffusely mottled or faintly streaked blackish on top of head and neck, mantle, back and scapulars, with bare yellow skin extending narrowly from gape and meeting yellow fleshy wattle on lower anterior ear-coverts, bordered below by sparsely feathered (variable) patch of black at base of bill extending back to wattle; feathered yellow stripe originating below eye (above wattle) curves up over and behind rear ear-coverts, enclosing small patch of dusky olive-grey on upper ear-

coverts; rump and uppertail-coverts brownish-grey to olive-grey; upperwing and tail dark olive-brown to dark brown, with yellow-olive edges on wing-coverts and remiges (contrasting olive-yellow panel on folded wing), and yellow-olive edges on tail; underside slightly paler and greyer than upperparts, olive-grey with yellow tinge, slightly greyer on chin and throat, diffuse and faint darker mottling or scaling on chin to breast and flanks; thighs light grey-brown, undertail light grey-brown, underwing off-white to buff-white with broad light grey-brown trailing edge and tip; iris dark brown to blue-grey, orbital ring yellow-orange; bill black, gape orange-yellow; legs slate-grey to blue-grey, soles yellow. Sexes alike in plumage, male slightly larger than female; female possibly generally more yellowish, especially below, but confirmation needed. Juvenile is like adult but duller and darker, with smaller wattle, also less olive above, with top of head and neck strongly barred or scaled with dark olive-brown, upperparts brownish with faint olive wash, and paler and less strongly olive below, chin to breast much more strongly mottled grey, merging to more yellow-olive on belly, vent and flanks and light buff-brown undertail-coverts; immature plumage, if present, undescribed. Races differ in extent of yellow and black on face and darkness of plumage: *procerior* is much darker than nominate, with yellow on face confined to narrow bare submoustachial stripe bordered above and more narrowly below by black feathering, greyish-olive ear-coverts narrowly edged at rear by small patch of yellowish-olive, upperparts darker olive and more strongly mottled and scaled darker (blackish-olive), and anterior underbody (particularly breast) more strongly mottled or scaled darker, also iris apparently darker; *taviunensis* is intermediate between previous and nominate. **VOICE.** Noisy, with variety of loud, vibrant, typically chiming or melodious vocalizations, usually in varied series; one of first birds to call in dawn chorus, and sometimes heard at night. A common call is a ringing "kee-kow", "ee-aa-oo" or "ke-too, ke-too", repeated often; and song described as "ti-ti-tui-tui-tur-twee" or gurgling whistled "churwee-churwee-churde-twee-twur". Loud bubbling alarm calls characteristic, typically given in response to predator, such as Common Barn-owl (*Tyto alba*); said to give soft liquid sucking notes in response to perched predator, such as goshawk (*Accipiter*), and loud, rolling bell-like call when predator in flight. Other calls include: whistling "ki-ki-ki-ki-ki"; varied musical or squawking whistles (possibly describing song); scolding and churring notes; brief, moderately high-pitched "cheew"; and subdued "kluk" intermittently during foraging. Duetting reported: birds usually on same branch, and maximum of 1 m apart, repeat loud, mellow, antiphonal patterns (somewhat more complex in Samoa than in Fiji); also duet in unison.

Habitat. Wide range of habitats, including mangroves (from seaward to landward edges), open coastal forest, casuarina forest, lowland, foothill and tall and low montane forest (including stunted moss forest on highest peaks), forest edge, and modified and artificial landscapes, including secondary vegetation (especially with coconuts), mixed and pure plantations of introduced pines (*Pinus*) and coconut plantations, sugar-cane crops; common in gardens in cities, towns and villages. In analysis of habitat use on Tutuila (American Samoa), appeared to depend on relatively undisturbed native forest despite use of wide range of habitats, and appeared to discriminate less among conditions within native forest than between native and non-native habitats; in non-native habitats, most abundant in plantations surrounded by native forest and with no introduced birds, and virtually absent from village habitats where abundance of introduced birds greatest. In Vava'u Group (Tonga), increased in abundance in less disturbed habitats, and much more common in mature forest, or submature/disturbed mature forest, than in villages, open plantations or wooded plantations/early successional forest. In Samoa, numbers in partly logged forest only slightly lower than those in unmodified forest; in another study, relative abundance high in forest, cleared forest and cultivated land, but low in urban habitat. Some variation between populations apparent. In Fiji, largely confined to mature forest and absent from coconut plantations and secondary vegetation on Taveuni, whereas most abundant in coastal coconut plantations on Lakeba. Preferred habitat on small offshore islands in Samoa varied: most abundant in tall, protected forest in interior on Nu'utele; slightly more abundant in successional forest than in plantation forest on Manono; and most abundant in native ridge forest and scarce in *Cocos*-dominated vegetation of the beach on Namua. In Samoa abundant at all altitudes; in Fiji, from near sea-level to 1450 m on Viti Levu and at 420–1060 m (commonest at high altitudes) on Taveuni; in Vava'u Group, in Tonga, absent or scarce on many small islands.

Food and Feeding. Primarily nectar, but also takes many arthropods (mainly insects, including caterpillars, and spiders), more so when breeding, and some soft fruits and berries; occasionally

small lizards, including geckos (Gekkonidae). Nectar taken from wide range of flowering shrubs, trees and palms, e.g. in American Samoa from small flowers of nutmeg (*Myristica inutitilis*) to the large crimson blooms of coral tree (*Erythrina variegata*), including asi (*Syzygium inophylloides*) and *Barringtonia* species, also from cultivated plants (including banana and coconut palms). In Fiji and Samoa, forages mainly in canopy and subcanopy, less often in lower storeys; occasionally forages on ground. Highly active, constantly flitting between flowering trees and shrubs, probing flowers and often hanging to do so; searches along branches and through foliage to glean arthropods; also sallies for flying arthropods, including moths (Lepidoptera). Bold, conspicuous. Usually in small groups of 3–4 individuals, but often singly or in twos (possibly pairs), and can congregate in small noisy flocks of 8–10 birds, and sometimes larger numbers (e.g. several dozen), in flowering plants (particularly in non-breeding periods). Aggressive, chasing and fighting with conspecifics and other species, and often displaces or chases *Myzomela*; attempts to defend nectar sources from Red-vented Bulbul (*Pycnonotus cafer*); reported as driving off mynas (*Acridotheres*) and Spotted Doves (*Streptopelia chinensis*).

Breeding. Breeds all year in Samoa, possibly with peaks in mid-summer and mid-winter, nest-building recorded Jan–Feb, dependent young mid-Jun and juveniles Feb and Oct, and specimens with definite indications of breeding Apr, Jun–Jul and Dec–Jan; in Tonga, eggs Aug, nestlings Jun and Aug, and fledglings May and Nov; throughout year in Fiji, with peaks Feb–Apr, Jun–Jul and Sept–Oct, and most pairs appear to raise two or more broods in a year. Territorial when breeding, driving larger species away from nest vicinity and physically attacking smaller birds (including *Myzomela cardinalis*). Nest rather fragile and cup-shaped, made of woven fine grass, vine tendrils, casuarina needles, other fibres and rootlets, often with spider web draped over exterior, in wet forest outside of nest sometimes heavily draped with green and moss-like liverworts; typically suspended by rim from horizontal fork in branch of shrub or tree 1–15 m above ground and well hidden in dense foliage; of 13 nests on 'Eua (Tonga), mean height 3 m and nine of the nests in *Citrus* tree; sometimes uses site of previous nest, even building over remnants of earlier one. Clutch normally 1 egg, sometimes 2, on Fiji said to be usually 2–3; no information on incubation and nestling periods; both parents feed nestlings and fledglings, the latter dependent for fairly long time.

Movements. No information; probably resident, with some local movements or dispersal to exploit flowering plants. On Tutuila, a broad, low increase in numbers through much of the hot wet season (roughly Dec–Apr) and a higher peak at some sites in Dec–Jan; changes probably relate mainly to local movements and concentrations of birds to exploit seasonally abundant food sources. In Samoa, recorded as apparent visitor on two (of seven) small offshore islands off Upolu, 0.7 km and 1.3 km over water from nearest populations. Specimen record from Kadavu, in SW Fiji, and may occur there occasionally.

Status and Conservation. Not globally threatened. Restricted-range species: present in Fiji EBA and in Samoan Islands EBA, and in Wallis and Futuna Secondary Area and in Tonga Secondary Area. Widespread and generally common or abundant over most of range. Estimated population in American Samoa 550,000 birds; considered the commonest landbird in American Samoa, and on Tutuila mean abundance at survey sites ranged from 0.25 to 18.88 birds per 8-minute survey; in survey of seven small offshore Samoan islands, the most abundant species on five islands. Tutuila population apparently reduced, after hurricanes, but recovering. Little-understood variation in distribution and abundance on islands throughout range, and absent from many islands where it may otherwise be expected to occur, including larger islands, e.g. in Fiji on Gau and Totoya (in Yasayasamoala Group), Vatoa (in Lau Group) and Ringgold Is. and on Kadavu (where replaced by *Xanthotis provocator*), and absent N & S outliers of Tonga. Possibly suffering adverse impact from introduced bird species in American Samoa: considered more common around villages in Manu'a Is, where no introduced birds present, than on Tutuila, where introduced Red-vented Bulbul, Common Myna (*Acridotheres tristis*) and Jungle Myna (*Acridotheres fuscus*) are common. Often attacked by Red-vented Bulbul in Fiji, although is also aggressive to that species (initiating aggressive interactions more than being recipient of them); no clear evidence that introduced species have restricted distribution of this or other honeyeater species. Nevertheless, in non-native forest found to be more abundant on Manono (Samoa) than in similar habitats on the large islands of Upolu and Tutuila, where introduced bird species are present.

Genus *GYMNOMYZA* Reichenow, 1914

143. Giant Honeyeater

Gymnomyza viridis

French: Méléphage vert **German:** Grünhonigfresser **Spanish:** Mielero Gigante
Other common names: Giant Forest/Giant Green Honeyeater

Taxonomy. *Tatara ? viridis* E. L. Layard, 1875, Taveuni, Fiji. Formerly placed in genus *Leptornis* or *Amoromyza*, both now defunct, and in past suggested as being most closely related to *Melidectes*. Races differ vocally, and may better be treated as two separate species. Two subspecies recognized.

Subspecies and Distribution. *G. v. viridis* (E. L. Layard, 1875) – Vanua Levu and Taveuni, in N Fiji. *G. v. brunneirostris* (Mayr, 1932) – Viti Levu, in W Fiji.

Descriptive notes. 25–31 cm. Large, robust honeyeater with moderately long, slender, and slightly decurved bill. Nominate race is wholly drab olive to dark olive (often appearing yellowish-olive in field), with faintly paler yellow-olive eyering and lores; above, tips and concealed inner webs of remiges and rectrices brownish-olive, contrasting slightly with upperparts; underwing pale grey-olive with darker olive-grey trailing edge and tip; iris grey to dark brown; bill and legs bright yellow. Sexes alike in plumage, male slightly larger than female. Juvenile undescribed (though see following). Race *brunneirostris* differs from nominate in olive-brown to blackish-brown bill, legs and feet; slightly shorter bill and longer tail, plumage also subtly paler and brighter olive, juvenile of this race has yellowish bill with brownish tip. **VOICE.** On Viti Levu (race *brunneirostris*), call described as repeated, ringing “keekow”, “kee-yow”, “keetoo” or “eekou”,

a characteristic yodelling cacophony that reverberates through forest and can be heard more than 1 km away; calling can begin several hours before dawn and continues until well after dark, though less often during middle of day (e.g. from 02:15 each morning in Aug–Sept; from 04:00 until after dawn during Jun–Jul). Much quieter on Vanua Levu and Taveuni (nominate race), with variety of calls (described as more like those of *Foulehaio carunculatus* but louder), including “keetoo” similar to that on Viti Levu, and loud melodious whistling gurgles with rapid mellow notes; said never to produce loud cacophonous yodelling heard on Viti Levu, but birds on Taveuni described as producing a remarkable volume of sound.

Habitat. Mainly large areas of contiguous mature primary forest, including hill and montane forest and stunted, mossy montane rainforest on highest peaks of Viti Levu; less often at forest edge, in degraded forest bordering mature forest, or in isolated tall trees at edge of secondary forest in grassland; occasionally in flowering or fruiting trees in agricultural areas close to mature forest. Appears intolerant of heavily logged forest without remaining tracts or patches of mature forest. Normally in hills and mountains; recorded at 460–1030 m (rarely lower) on Taveuni and from 80 m to 1310 m on Viti Levu.

Food and Feeding. Mainly nectar (including from wild banana, coconut palms, and pandanus), also arthropods (including insects and their caterpillars, and spiders); small berries, soft fruit; occasionally lizards. Usually forages in outer canopy or subcanopy of tall forest, occasionally lower (most often middle levels), including on ground. Active, leaping about in canopy or understorey; said to creep up tree trunks, but confirmation needed. Forages actively for arthropods, including by gleaning. Shy and retiring, heard more often than seen, but sometimes perches in open. Sociable and pugnacious; usually seen singly or in twos (possibly pairs), but in Fiji sometimes in noisy flocks at food sources. Aggressive to some other species, such as Collared Lory (*Phigys solitarius*), in flowering trees.

Breeding. Little known. Breeding thought to occur at least Jun–Oct, and one juvenile recorded late Aug. One nest found, a fairly substantial basket or cup made of rootlets (probably of epiphytes), external diameter c. 20–25 cm, suspended from leafy branch c. 18–20 m above ground in outer foliage of large canopy tree. No information on clutch size or eggs, nor on incubation and nestling periods; only single dependent juveniles ever observed, and thought that fledglings dependent for a long period, possibly 2–3 months or more.

Movements. No information; apparently resident. It is suggested that its dispersal ability is weak. **Status and Conservation.** Not globally threatened. Restricted-range species: present in Fiji EBA. Fairly common in suitable habitat. Studies of calling birds on Viti Levu suggested an island population of c. 142,000 calling individuals; another study of territory size suggested an island population of 60,000 pairs. Populations on all three islands considered reasonably large (apparently not uncommon), and appear not to be declining significantly. Occurs in nearly all protected areas with good forest, and is protected under Fijian law. Does, however, require large areas of contiguous rainforest, and past and present loss and degradation of mature forests are an ongoing threat. Although industrial logging has stopped on Viti Levu and Taveuni, forests on all three islands are being slowly degraded by logging for domestic use and agricultural expansion.

Bibliography. Anon. (2007a), Beckon (1993), Blackburn (1971), Brown & Child (1975), Butchart & Stattersfield (2004), Clunie (1984), Diamond (1972b), Gorman (1975), Holyoak (1979), Langham (1984, 1989), Masibalavu & Dutton (2006), Mayr (1932, 1944b, 1945b), Orenstein (1979), Pernetta & Watling (1978), duPont (1976), Pratt *et al.* (1987), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Watling (1982a, 2001).

144. Mao
Gymnomyza samoensis

French: Méléphage mao **German:** Maohonigfresser **Spanish:** Mielero Mao
Other common names: Black-breasted/Mao Honeyeater

Taxonomy. *Merops samoensis* Hombron and Jacquinot, 1841, Upolu, Samoa. Relationships not known; formerly placed in genus *Leptornis* or *Amoromyza*, both now defunct, and has been suggested as being closest to *Melidectes*. Few specimens from American Samoa (Tutuila; now extinct) on average slightly larger and somewhat darker, especially on head, than other populations, but differences too trivial to warrant naming of geographical races. Monotypic. **Distribution.** Savai'i and Upolu, in Samoa.

Descriptive notes. 28–31 cm. Large dark honeyeater with long, gently decurved bill. Appears wholly dark at distance; head, neck and breast sooty black to olive-black, conspicuous olive streak from below eye across upper ear-coverts; largely dusky olive-brown or dark brown upperbody and underbody, varyingly washed olive-green, with rump and uppertail-coverts slightly paler than rest of upperparts, and undertail-coverts slightly paler and browner than rest of underbody; uppertail and upperwing dark olive-brown, olive-green outer edges of rectrices, greater coverts and remiges (olive-green wash on folded wing); iris brownish-grey

to brown; bill black; legs black to blackish-grey, soles yellow. Sexes alike in plumage, male larger than female. Juvenile is like adult, but head and underbody less strongly black. **VOICE.** Considered noisy. Call described as a loud cat-like wailing “mee-aa-oo” or a series of low, hoarse, nasal mewling notes, at times rising in pitch, followed by clearer high-pitched phrases and developing into loud, upslurred yelps before subsiding again; given in bouts lasting for up to 1 minute or more (one call comprising at least 55 notes), and heard most often in morning and evening. Other calls include nasal, downslurred “yaaw”; loud, mechanical-sounding “chlip”; and short squeaky notes.

Habitat. Native forest and forest edges, and cultivated land with remnants of rainforest, e.g. in steep valleys, in foothills and montane areas; greatest densities in craters at high altitude in least disturbed forest. Also seen in cinder cone, in heathland scrub, and on steep slopes along rivers. Reported as visiting coconut trees near coast (probably in periods of stress after cyclones), and apparently was more widespread in lowlands in the past. Recorded at 760 m and above 900 m, and said to be commoner on the very tops of peaks; found in remaining rainforest at up to 1500 m. Recently found to be present in upland areas with disturbed forest next to cattle farms and plantations.

Food and Feeding. Nectar, arthropods (mainly insects) and small fruit. Forages usually in crowns of trees, or in subcanopy; seen foraging in coral trees (*Erythrina*), the blossoms of which contain nectar and many insects; said to forage also on moss-covered branches. Forages also in *Albizia chinensis* and *Paraserianthes falcata*; searches intensively in rotten wood of dead branches of these large trees, digging into the soft wood and probing with bill, sometimes while hanging head downwards; observed to extract and swallow insect larvae. Inconspicuous, heard more often than seen. Usually in pairs, partners seeming to stay close together. Competes with many other species at flowers of *Erythrina*, where it is dominant, attacking all other species except Samoan Starling (*Aplonis atrifusca*); in presence of a group of latter species, performs song flights as an indirect sign of territoriality.

Breeding. Nest high up, in fork of tree, with 2–3 eggs. No other information.

Movements. Sedentary, with some local movements.

Status and Conservation. ENDANGERED. Restricted-range species: present in Samoan Islands EBA. Rare. Total population small (estimate of 1000–2500 individuals), fragmented and apparently declining, and small subpopulations may not be viable. Formerly occurred on Tutuila, in American Samoa, but now extinct; last collected in 1924, sight records in 1933, and last unconfirmed report in 1977; status on Tutuila, however, not certainly known, and may have occurred only as a visitor from Samoa. Thought to have been formerly widespread in forests in Samoa, from coasts to mountains, but range dramatically reduced and the species appears to have become rarer within its current range. Decline largely attributed to loss of forest habitat, and degradation of remaining habitat, with Samoan forests now open and patchy, and so supporting fewer birds and becoming more vulnerable to weed invasion. Apparently dependent on remaining patches of primary forest, but remaining areas of upland forest threatened by slash-and-burn cultivation, farmers using roads from logged lowland forests to gain access to formerly inaccessible land; forest quality further reduced by invasion of aggressive exotic trees, spread of which is aided by cyclones and by the planting. Cyclones a significant threat; during the two most powerful recent cyclones, in 1990 and in 1991, forest canopy cover was reduced from 100% to 27%, and populations of present species were reduced, e.g. disappeared from lowland forests in O Le Pupu-pu'e National Park (on Upolu) between 1982 and 1991 following these two cyclones. Fires in low-rainfall forests, hunting (despite national bans on hunting native birds and bats that have been in place for more than ten years) and introduced rats (*Rattus*) may also pose a threat to the species. Occurs in some proposed and existing protected areas, but these have suffered damage from cyclones and O Le Pupu-pu'e National Park is threatened by logging and cattle-farming. Local peoples often shot this species when they saw it near villages, as it was considered a bird of ill omen.

Bibliography. Anon. (2006b, 2007a), Ashmole (1963), Banks (1984), Beichle (2008), Beichle & Baumann (2003), Bellingham & Davis (1988), Butchart & Stattersfield (2004), Collar *et al.* (1994), Craig (2005), Freifeld *et al.* (2001), Lovegrove *et al.* (1992), Mayr (1932, 1944b, 1945b), Muse & Muse (1982), Orenstein (1979), Park *et al.* (1992), duPont (1976), Reed (1980), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Tarburton (2001), Watling (1982a, 2001), Whitmee (1875).

145. Crow Honeyeater

Gymnomyza aubryanus

French: Méléphage toulou **German:** Rotgesicht-Honigfresser **Spanish:** Mielero Cuervo
Other common names: Red-faced Honeyeater

Taxonomy. *Leptornis Aubryanus* J. Verreaux and Des Murs, 1860, New Caledonia.

Previously placed in genus *Leptornis* and *Leptomyza*, both now defunct. Relationships unclear, and study needed; formerly suggested as being most closely related to *Melidectes*. Monotypic.

Distribution. New Caledonia.

Descriptive notes. 35–42.5 cm; male 211–284 g, two females 152 g and 159 g. Very large and distinctive, corvid-like honeyeater, with long, pointed and decurved bill, long rounded wings and fairly long neck, and long graduated tail. Plumage is glossy black, with sparsely feathered blackish lores, large yellow to orange-red fleshy orbital ring (broken at rear of eye) and yellow wattles at rear edge of orbital ring; remiges and rectrices glossy brownish-black; feathers of head, hindneck, throat, breast and belly have pale yellowish shafts, giving finely streaked appearance in close view; iris dark brown; upper mandible and tip

of lower mandible black to grey-black, yellowish to orange base of lower mandible and gape (contrary to statements that lower mandible simply blue-black); legs pale yellow to yellow-orange (reported also as blue-grey). Sexes alike in plumage, male noticeably larger than female; female said also to be less strongly black. Juvenile is largely undescribed, has tuft of yellow feathers on ear-coverts. **Voice.** Quiet outside breeding season. During breeding season the first species to sing in morning, roughly an hour before sunrise; song a loud, melodious ringing note. Also gives crow-like call “wa-wa” (possibly in alarm or agitation), a low sibilant cry during foraging, and harsh croak in flight.

Habitat. Mainly dense, humid, primary rainforest, usually on ultrabasic soils; recorded also in dry forests (at Pouémbout), which may refer to niaouli (*Melaleuca leucadendra*) savanna woodland or to the highly threatened sclerophyll forest (which covers less than 3% of New Caledonia’s land area), also in isolated stands of stunted forest within maquis, up to 2 km from more extensive stands of forest. To 1000 m, with recent records from 100 m to 850 m.

Food and Feeding. Diet insects, including beetles (Coleoptera) and small flies (Diptera), large spiders (Araneae), and nectar from flowers. Forages in canopy or middle storey, often in flowering trees; hangs and clambers about the ends of branches to reach flowers. Inconspicuous and shy; usually seen singly or in twos (probably pairs), but formerly reported also in small parties. Once seen to displace a New Caledonian Cuckoo-shrike (*Coracina analis*).

Breeding. A nest under construction in Sept (1982) and another on which bird thought to have been sitting in mid-Oct. First nest cup-shaped and thick-walled, c. 20 m above ground, apparently supported in fork of several thin branches. Estimated territory size 0.5–0.75 km². No other information.

Movements. No information. Probably sedentary.

Status and Conservation. ENDANGERED. Restricted-range species: present in New Caledonia EBA. Rare. Estimated total population small, between 1000 and 3000 individuals in 2000–2002, and this probably an overestimate. Population thinly distributed, fragmented, and thought to be in continuing decline. Most recent records scattered in S of Grande Terre, mainly in C mountains from Mt Humboldt, through Rivière Bleue Park (c. 18 known pairs in study area within park, with estimated total of 160 pairs) to Mt Dzumac, with a few records in N (on Mt Panié and Pouémbout). Appears to be localized and uncommon even in preferred habitat, and reasons for absence from apparently suitable habitat not known, but suggesting an unknown specialization. Loss and degradation of forest from logging, nickel-mining and fires likely to pose some threat. Cause of apparent continuing decline in Rivière Bleue Park not certainly known, but no successful nests or juvenile birds have been seen here. Although decline possibly due, at least partly, to predation by introduced rats (*Rattus*), the related and smaller *G. viridis* of Fiji appears to be unaffected by rats.

PLATE 51

Family MELIPHAGIDAE (HONEYEATERS) SPECIES ACCOUNTS

Genus *MELITHREPTUS* Vieillot, 1816

146. Black-chinned Honeyeater

Melithreptus gularis

French: Méliophage à menton noir

Spanish: Mielero Barbinegro

German: Schwarzkinn-Honigschmecker

Other common names: Black-throated Honeyeater; Golden-backed Honeyeater (*laetior*)

Taxonomy. *Haematops gularis* Gould, 1837, interior of New South Wales, Australia.

Forms a superspecies with *M. validirostris*. Race *laetior* often treated as a separate species, but intergradation with nominate over broad zone in E Australia (Queensland S to NC New South Wales); further research needed. Additional proposed races are *normantoniensis* (from Normanton, in NW Queensland) and *carpentarianus* (Homestead, on Campaspe R. in E Queensland), both regarded as intergrades, and *parus* (Exmouth Gulf, in Western Australia), synonymized with *laetior*. Two subspecies recognized.

Subspecies and Distribution.

M. g. laetior Gould, 1875 – W & N Western Australia E to NW & N Queensland (around S & E Gulf of Carpentaria and S Cape York Peninsula), thence S to NC New South Wales.

M. g. gularis (Gould, 1837) – N & E Queensland (from S Cape York Peninsula) S to N foothills of Great Divide in N & NC Victoria; SE South Australia (Fleurieu Peninsula and S Mt Lofty Ranges).

Descriptive notes. 14–16.5 cm; 18.5–23.2 g, male 20.5–22.5 g, one female 19 g (nominate), male 15–20 g and female 16.1–20.2 g (*laetior*). Nominative race has neat black cap covering most of top and side of head and neck, arc of bare bright blue skin over top of eye, and conspicuous white crescent extending from rear edge of blue orbital arc across nape; malar area and side of throat white, black chin grading to grey-brown on middle of throat; upperbody largely olive-green, narrow olive-buff band on uppermost mantle, yellow-olive rump and uppertail-coverts; uppertail and upperwing largely brown, grey tinge on secondary coverts; breast pale brownish-grey, grading to off-white on belly, vent and undertail-coverts, and with grey-buff flanks; undertail grey-brown, underwing creamy buff with brown trailing edge and tip; iris brown, sometimes reddish-brown;

bill and gape grey-black to black; legs orange-rufous. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult but duller and browner overall, cap brown, bare skin above eye dull blue, band on nape off-white, upperbody olive-brown, grading to olive-green on lower rump and uppertail-coverts, chin blackish, grading to brown on centre of throat and brownish-grey on breast, and to white from belly to undertail-coverts, iris dark brown, bill initially wholly orange but gradually develops darker patches, upper mandible quickly becomes orange-brown, legs orange; immature like adult, sometimes a few brown

juvenile feathers retained on crown, nape and rump, and bill takes c. 12 months to become completely black. Race *laetior* is patterned like nominate, but upperbody largely golden yellow-olive, with narrow bright yellow band across uppermost mantle and bright yellow rump, underparts off-white, with grey wash across breast and flanks, and bare skin above eye pale jade-green to straw-yellow. Voice. Noisy, calling often, loudly and throughout year, more so when breeding; voice clear and ringing. Song rich, complex and varying, described as strong, shrill piccolo notes, repeated 2–4 times, sometimes for 10–15 minutes; pair-members often sing in reply to one another. Both sexes also give loud, harsh, grating, croaking or rollicking “chee-chee”, “creep-creep-creep” and “chip-chip-chip, chur-chur-chur-chur”, sometimes in flight; and loud, single or double, whistling or bell-like note. Other calls include single harsh note; cheeps and chirrups when gathering nest material; soft, deep, guttural notes; warbling; and undescribed distress call.

Habitat. Mainly open eucalypt forests and woodlands. In E & S Australia, mainly in forests and woodlands dominated by box and ironbark eucalypts, e.g. mugga ironbark (*Eucalyptus sideroxylon*), grey ironbark (*Eucalyptus paniculata*), grey box (*Eucalyptus moluccana*), white box (*Eucalyptus albens*); less often in other mixed open eucalypt forests or woodlands of smooth-barked gums, stringybarks, ironbarks and tea-trees (*Leptospermum*), or such associations interspersed with clumps of other trees, such as *Banksia*, *Callitris* or *Casuarina*. In N, found in tall open woodlands of stringybark eucalypts or bloodwoods (*Corymbia*), or riparian associations dominated by paperbarks (*Melaleuca*), eucalypts or acacias, or combinations of these. In arid and semi-arid regions, often in riparian woodlands dominated by river red gum (*Eucalyptus camaldulensis*) or coolibah (*Eucalyptus*

coolabah), sometimes with dense thickets of paperbarks and *Callistemon*, or shrubby understorey of *Acacia*. Occasionally in gardens.

Food and Feeding. Mainly nectar and invertebrates (mostly insects); sometimes honeydew, and very occasionally seeds. Forages mostly in trees (mainly *Eucalyptus*), occasionally in understorey shrubs (e.g. *Astroloma*), saplings or creepers; in canopy among outermost flowers, foliage and twigs, occasionally on branches and trunks; very occasionally forages on ground. Probes flowers for nectar; if flower long and tubular, may steal nectar by piercing base of flower before probing. Obtains insects by gleaning foliage or flowers, or from beneath bark of trees, sometimes by pulling at bark; occasionally takes flying insects in air by sallying. Often hangs upside-down to reach flowers. Usually in pairs or in small groups of up to twelve or so individuals; occasionally forages with other species of honeyeater, particularly in flowering trees; once seen in mixed-species feeding flock of 40–45 honeyeaters of six genera.

Breeding. Race *laetior* not well known but mainly Jan–Aug, occasionally to early Oct (one clutch late Mar, nestling mid-Jun); for nominate race recorded in all months except May but mainly austral spring, with estimated start of clutches Jan–Feb and Aug–Sept in NE and eggs Jun–Dec in New South Wales. Often breeds co-operatively, but also solitarily. Nesting material collected by both sexes, and nest sometimes built by more than two individuals; nest cup-shaped, usually of fibrous bark woven together with hair, wool or fur, and occasionally spider webs, cocoons or grass, usually lined with wool, hair or fur, external diameter 7 cm, depth 7–6 cm, internal diameter 5–1 cm, depth 5–3 cm; usually suspended in crown of tall tree (mainly *Eucalyptus*), less often in shrub, usually in uppermost branches, well concealed by foliage, 1–25 m (mean 8–4 m) above ground. Clutch usually 2–3 eggs; no information on incubation and nestling periods; nestlings and fledglings fed by both parents and by any auxiliaries present. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*).

Movements. Mainly resident; sometimes considered nomadic, and changes in numbers or apparent movements reported at many sites where considered resident, but many such movements probably local. Increases in numbers often associated with flowering of trees. Occasionally undertakes longer movements, hundreds of kilometres beyond normal range. Vagrants of race *laetior* recorded in Cooper Creek Drainage Basin (SW Queensland) and in NE South Australia.

Status and Conservation. Not globally threatened. Rather uncommon. No estimates of total population, but recorded densities of up to 0.01–1.03 birds/ha.

147. Strong-billed Honeyeater

Melithreptus validirostris

French: Méléphage à bec fort **German:** Starkschnabel-Honigschmecker **Spanish:** Mielero Picudo
Other common names: Black-capped Honeyeater

Taxonomy. *Haematops validirostris* Gould, 1837, Van Diemen's Land = Tasmania. Forms a superspecies with *M. gularis*. Birds from King I (in Bass Strait) described as race *kingi*, but differences from those elsewhere in range appear too trivial to warrant naming of geographical races. Monotypic.

Distribution. Islands in Bass Strait (King I, Flinders I) and Tasmania.

Descriptive notes. 15 cm; male 23–30 g, female 17–25 g. Has neat black cap covering top and side of head and hindneck, arc of bare light blue to blue-green or pale green skin over top of eye, and broad white (sometimes smudged grey-brown) crescent-shaped band across nape; sharply demarcated white malar area grades into off-white on sides of chin and throat, with small black patch in centre of chin and mid-line of throat; upperparts largely olive-grey, mottled olive-green, rump and uppertail-coverts brighter and more uniformly olive; uppertail dull olive; upperwing mostly grey-brown, dark brown primary coverts and

rest of remiges, faint olive tinge on edges of primary coverts (in fresh plumage); underbody light brownish-grey, undertail brownish-grey, underwing brownish-buff with broad brown trailing edge and tip; iris red-brown; bill and gape black; legs brown to dirty pink. Sexes alike in plumage, male larger than female. Juvenile is patterned like adult, but with duller, brown-black cap, lemon-yellow malar area and band across nape, olive-green mottling extending from mantle to hindneck, distinct olive edges and tips on primary coverts, bill brown, grading to orange-buff at tip, gape orange-buff and swollen, iris dark brown to reddish-brown, bare skin over eye initially absent, then develops small light blue patch, orbital ring conspicuous orange-buff, legs orange to dark pink. **VOICE.** Noisy. Continuous loud short, sharp “cheep” notes, as single or double notes, or in rattling cadence; soft “cheep” as contact call when nesting, but not at other times. Other calls include harsh, aggressive “churr” in alarm or when defending breeding territory, and sharp whistle when raptor detected nearby.

Habitat. Mainly mature, wet sclerophyll forests, including stands of mountain ash (*Eucalyptus regnans*) or alpine ash (*Eucalyptus delegatensis*), especially in gulleys supporting an understorey either of sclerophyllous shrubs or of cool temperate rainforest; common also in dry sclerophyll forest dominated by eucalypts, on drier slopes and mountain ridges, including those with understorey of sclerophyllous shrubs, grass or sedges, particularly during winter. Sometimes in cool temperate rainforest dominated by antarctic beech (*Nothofagus cunninghamii*), Huon pine (*Dacrydium franklinii*), celery-top pine (*Phyllocladus aspleniifolius*) or blackwood (*Acacia melanoxylon*); subalpine eucalypt forest or woodland; low coastal scrub or heathland; closed wet scrub beside wetlands or in gulleys and dominated by *Acacia*, *Leptospermum*, *Melaleuca* and *Banksia*, some-

times with emergent eucalypts; and buttongrass (*Gymnoschoenus sphaerocephalus*) sedgeland with scattered emergent eucalypts. Sometimes in parks and gardens.

Food and Feeding. Usually invertebrates (mainly insects), sometimes also nectar and fruit. Forages in canopy, subcanopy and understorey of trees and shrubs. Mostly probes or gleans bark, including pendent bark, of large branches and trunks of rough-barked or smooth-barked eucalypts, or among foliage and twigs; occasionally feeds at flowers, and very occasionally among leaf litter on ground, and sometimes makes aerial sallies. Often forages in manner of an Australasian treecreeper (Climacteridae), moving up and down trunks of trees, searching crevices, and pulling off pieces of loose or pendent bark to expose prey. Techniques include several unique within genus: flaking, in which bird flicks off small pieces of bark, or brushes aside loose substrate with sideways sweeping motion of bill; prying, in which it uses bill or head to lever off strips of bark; and pulling, by grasping, pulling and tearing to remove strips of bark. Active and confiding. Mostly in small flocks, but sometimes in congregations of up to 40, once of 70, individuals; often forages with *M. affinis*.

Breeding. Season primarily late winter to mid-summer, Jul to mid-Jan, with eggs recorded Aug–Dec and nestlings mid-Aug to early Sept. Occasionally breeds co-operatively, but no details. Nest a small, deep cup, usually made of strips of bark (sometimes encrusted with lichen), sometimes also grass, leaves, wool and spider web, usually lined with soft bark fibres, plant down, wool, hair, fur or paper, sometimes unlined, external diameter 10–2 cm, depth 8–9 cm, internal diameter 6–4 cm, depth 3–8 cm; usually suspended by rim in eucalypt tree or sapling, or in other tree or shrub in understorey, occasionally in crown of tree-ferns, usually in outer foliage or in outer branches and twigs at top of nest plant, 2–11 m (mean 4–6 m) above ground. Clutch 3–4 eggs, usually 3; incubation probably by both sexes, and both also feed and defend nestlings; no information on duration of incubation and nestling periods. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*).

Movements. Resident; some local movements from wet sclerophyll forest into dry sclerophyll during winter. Sometimes considered nomadic, especially after young fledged, but this probably describing local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tasmania EBA. Widespread in Tasmania. No estimates of total population, but recorded at densities of up to 2.5 birds/ha.

Bibliography. Barrett *et al.* (2006), Blakers *et al.* (1984), Cale (1994), Campbell, A.G. (1903), Campbell, A.J. (1900), Dove (1907, 1916), Fielding (1979), Green (1989, 1995), Green & McGarvie (1971), Griffioen & Clarke (2002), Henderson & Green (1982), Higgins (1999), Higgins *et al.* (2001), Keast (1968a, 1968b), Littler (1910), Mellor & White (1913), Mollison (1974), North (1907), Noske (1983), Ratkowsky & Ratkowsky (1980), Ridpath & Moreau (1966), Schodde & Mason (1999), Sharland (1925, 1958), Slater (1994), Taylor *et al.* (1997), Thomas (1979, 1980, 1986), Waite (1976).

148. Brown-headed Honeyeater

Melithreptus brevirostris

French: Méléphage à tête brune **German:** Braunkopf-Honigschmecker **Spanish:** Mielero Cabecipardo
Other common names: Short-billed/Least Honeyeater, Large-billed/Long-billed Honeyeater

Taxonomy. *Meliphaga brevirostris* Vigors and Horsfield, 1827, Sydney region (Parramatta), New South Wales, Australia.

Races intergrade where they abut: *pallidiceps* intergrades with nominate in broad hybrid zone inland of Great Divide in Victoria, and with *leucogenys* in narrow zone in South Australia (extending S from about Port Augusta and S Flinders Ranges to Yorke Peninsula). Proposed race *augustus* (described from Port Augusta) relates to latter intergrading population. Five subspecies recognized.

Subspecies and Distribution.

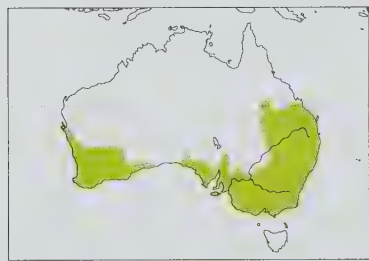

M. b. leucogenys Milligan, 1903 – S Western Australia (from Peron Peninsula E to W Nullarbor Plain); also S South Australia (Eyre Peninsula).

M. b. pallidiceps Mathews, 1912 – inland plains and W slopes of Great Divide in S Queensland, W & C New South Wales and N Victoria, extending W into S South Australia.

M. b. brevirostris (Vigors & Horsfield, 1827) – E slopes of Great Divide New South Wales and both slopes in Victoria, extending W into SE South Australia.

M. b. magnirostris North, 1905 – Kangaroo I (South Australia)

M. b. wombeyi Schodde & Mason, 1999 – Otway Ranges and S Gippsland, in S Victoria.

Descriptive notes. 11.5–14 cm; male 12–16 g and two females 14.1 and 17 g (nominate), male 11–14.2 g and female 12–16 g (*pallidiceps*), male 11–14.5 g and female 11–15 g (*leucogenys*), male 17–19.3 g and female 15.7–20.5 g (*magnirostris*), male 17.5–20 g and female 16.5–18 g (*wombeyi*). Nominata race has dull brown cap covering top and side of head and hindneck, bare creamy-yellow skin around eye (broadest above and behind eye), and buff crescent-shaped band across nape (normally not reaching bare skin around eye); off-white chin and throat; upperbody dull olive-green, brighter on rump and uppertail-coverts; uppertail brown

with narrow olive-green edges; upperwing brown, diffuse buff edges on coverts, fine brownish-grey to off-white edges on remiges; underbody buff-white with pale rufous wash, strongest on flanks and undertail-coverts; undertail brown; underwing brown, off-white patch across bases of remiges; iris reddish-brown; bill black, gape grey; legs light brown to brownish-grey, more orange on feet, especially soles. Sexes alike in plumage, male slightly larger than female. Juvenile is patterned like adult, but with pale crescent on nape inconspicuous, mostly brown upperparts, light olive outer edges of tertials and secondaries (visible on folded wing), bill orange-yellow with dark brown tip and culmen, gape conspicuous and orange, bare skin around eye turquoise. Races differ in size, in darkness of plumage and in extent of grey-brown scalloping on crown: *pallidiceps* is significantly smaller than nominate, paler overall, with cap strongly scaled brownish-grey (can appear uniformly brownish-grey when very fresh); *leucogenys* also is smaller and paler than nominate, with cap paler and more uniform (but darker and less scaly than previous), and with distinct orange tinge in bare skin around eye; *magnirostris* is larger than nominate, with noticeably longer bill, darker cap, more diffuse white nuchal band, slightly darker underbody; *wombeyi* is larger and darker than others, with almost black-brown cap, diffuse napeband (much as previous), darker olive upperparts, darker below, with throat, breast and

anterior flanks brownish-grey, grading to buff on belly and to brownish-grey with buff wash on undertail-coverts. Voice. Noisy, calling often. Main call a repeated sharp, unmusical and moderately high-pitched "chip", "click", "chick" or "kt", as contact call during feeding or from flocks in flight; also an animated staccato "chip-chip-chip...", starting with separate notes, accelerating, then decelerating and ending with separate "chip" notes; flat hard trill in alarm. Other calls include trilling, rattling, twittering, grating, rasping and chuckling sounds.

Habitat. Mostly dry, open *Eucalyptus* forests and woodlands, often with well-developed shrubby understorey of *Callitris*, *Casuarina*, *Melaleuca*, *Banksia* or *Acacia*. Also other *Eucalyptus* forests, including wet sclerophyll forests in gulleys, riparian or littoral forests or woodlands, and mallee eucalypt woodland or shrubland. Less often in open forests or woodlands dominated by other trees such as *Acacia*, *casuarina* or *Callitris*, sometimes mixed with eucalypts, including low coastal *Banksia-Eucalyptus* woodland, mallee shrubland dominated by broombush (*Melaleuca uncinata*) or of mallee eucalypts mixed with other shrubs such as sugarwood (*Myoporum platycarpum*), belah (*Casuarina cristata*), *Senna*, *Dodonaea* or *Eremophila*; or occasionally in open heathland of *Banksia*, *Leptospermum*, *Melaleuca*, *Casuarina* or *Dryandra*. In temperate, subtropical and semi-arid zones, from coasts to tree-line in subalpine areas.

Food and Feeding. Arthropods (especially insects, also spiders), nectar and manna, lerp and honeydew; known also to prey on eggs of other small birds. In South Australia, 65% of food eaten was insects and 35% nectar. In Victoria, ate manna, honeydew and lerp for most of year and nectar from mistletoe (e.g. of genus *Amyma*) and other plants during spring (when little manna or lerp available), e.g. of 142 foraging observations at one site, 52% of feeding on manna from manna gum (*Eucalyptus viminalis*), 18% on honeydew from psyllids, 23% on nectar, and 7% on insects collected from foliage or aerially. Forages mainly in canopy of trees (especially mature *Eucalyptus*), including sometimes in mistletoes (e.g. of genus *Amyma*), less often in shrubs (e.g. *Acacia*, *Adenanthos*, *Correa*, *Draandra*, *Grevillea*) and saplings in middle storey and understorey. Searches mainly on bark of branches, among foliage and twigs, and outermost flowers. Insects taken by gleaning, occasionally by salting in air. Probes flowers for nectar, rotating bill rapidly around base of style; sometimes hangs upside-down to probe pendulous flowers; sometimes steals nectar by piercing bases of tubular flowers. Lerp, manna and honeydew taken by gleaning and probing. Proportions of time or feeding observations directed at different food types, and of substrates and foraging method used (which correlated with food type), vary among studies; of 146 observations of foraging in N New South Wales, 89.7% in foliage, 8.2% among flowers, 1.4% on branches, and 0.7% on trunks (and not seen to forage on ground or aerially), whereas, of 375 observations of foraging in Mt Lofty Ranges (South Australia), 20% in foliage, 25% on twigs and 55% on branches (and not recorded as feeding on trunks of trees or in saplings). Height of foraging can also vary seasonally, e.g. in wet mountain ash (*Eucalyptus regnans*) forests in Victoria, foraged mainly in canopy during summer, taking nectar only in peak flowering season, and mainly in understorey in winter, when nectar of *Correa lawrenceana* available. Active and vocal. Mostly in small flocks of 5–15 individuals, but up to 20 sometimes gather in flowering eucalypts.

Breeding. Season mainly late winter to mid-summer, but breeding recorded in all months except May, most records of breeding and nearly all those of eggs late Aug to mid-Jan; usually double-brooded. Regularly breeds co-operatively, but often solitarily. Both sexes collect nesting material, but possibly only female builds; nest a small, neat and deep cup, usually of strips of stringybark or grass, woven with hair, fur, wool, spider web and egg sacs, often lined with hair, fur, wool, feathers including down, or plant down, external diameter 5.7–7.6 cm, depth 4.4–7.6 cm, internal diameter 4.4–5.1 cm, depth 3.8–5.1 cm; usually suspended in outer foliage in top of tree, especially eucalypt, or tall shrub, sometimes in sapling, 0.7–2.4 m (mean 6.6 m) above ground. Clutch usually 3 eggs, sometimes 2; incubation by both sexes and, at least sometimes, auxiliaries, no information on duration; chicks fed by both parents and by any auxiliaries present, nestling period once more than 11 days and once 15 or more days. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*), by Shining Bronze-cuckoo (*Chrysococcyx lucidus*) and probably by Horsfield's Bronze-cuckoo (*Chrysococcyx basalis*). From 11 eggs in six nests, overall success 0.17 young fledged per nest; of 29 nests for which outcome known, 20 (69%) fledged at least one young. **Movements.** Generally resident, with local movements within large home ranges in response to availability of food. Described as migratory or nomadic in some areas, although such claims may be referring to local movements, e.g. near Canberra groups wander over area of 5–8 km², and near Kellerberrin (Western Australia) groups ranged up to 3.1 km along well-vegetated road verges. Other seasonal patterns may result from movements between habitats, e.g. around Sydney (New South Wales) moves from forest to spend autumn and winter in coastal heathland. In some areas where present throughout year, recorded more often in autumn or winter than at other times, possibly because birds form mobile and conspicuous flocks outside breeding season; in other areas occur throughout year but irregularly, with no seasonal trends. Possibly migratory in some parts, especially in SE New South Wales, being recorded apparently on passage, sometimes with known migratory species such as *M. lunatus*.

Status and Conservation. Not globally threatened. Widespread and locally common; rare in extreme SW Western Australia (including on Swan R Plain). No estimates of total population; recorded densities of up to 3.76 birds/ha.

149. White-throated Honeyeater

Melithreptus albogularis

French: Méliphage à menton blanc

German: Weißkinn-Honigschmecker

Spanish: Mielero Goliblanco

Other common names: Grey/White-chinned Honeyeater

Taxonomy. *Melithreptus albogularis* Gould, 1848, Port Essington, Northern Territory, Australia. Closest to *M. lunatus* and *M. affinis*, the three species characterized by tapering white napeband, uniformly citrine dorsum, white breast to vent, slender sepia-toned feet, and black of head extending

to side of breast. Races intergrade where they abut in Burdekin–Endeavour rivers region of NE Australia. Birds in New Guinea currently included in nominate race, but racial identity requires confirmation. Two additional proposed races, *subalbugularis* (from Derby, in N Western Australia) and *schoddei* (Clarke Range, in E Queensland), are synonymized with, respectively, nominate race and *inopinatus*. Two subspecies recognized.

Subspecies and Distribution.

M. a. albogularis Gould, 1848 – disjunctly in S, NE & SE New Guinea (S Trans-Fly from Kurik E to Oriomo R; middle reaches of Markham R; upper Musa R, lower Pongau R and Oro Bay and, S of Owen Stanley Range, Bereina E to Kupiano); Western Australia (from Kimberley and Broome) and Top End of Northern Territory (S to Barkly Tableland) E to NE Queensland (Cape York Peninsula S to Burdekin–Mitchell Drainage Basin), including numerous offshore islands.

M. a. inopinatus Schodde, 1989 – E Queensland (from Burdekin–Mitchell Drainage Basin) S on E slopes of Great Divide and adjacent coast to NE New South Wales (S to Macleay R).

Descriptive notes. 11.5–14.5 cm; male 10–13 g and female 9–12.5 g (nominate), male 12–15 g and female 10–15 g (*inopinatus*). Nominate race has neat black cap covering top and side of head and hindneck, arc of bare white to pale bluish-white skin over eye (report of orange-red arc in New Guinea considered to be in error), long narrow white crescent-shaped band across nape; black of lower hindneck extends down to side of upper breast (appearing as small black spur in some postures); upperparts largely olive-green, slightly brighter on rump and uppertail-coverts; uppertail mostly olive-yellow with duller

centre when closed, browner with olive sides when spread; upperside largely olive-brown, remiges with olive-green outer edges (conspicuous panel on folded wing); chin, throat and underbody (except side of upper breast) white; undertail grey-brown, underwing off-white with broad brown trailing edge and tip; iris reddish-brown; bill and gape black; legs pink with dark brown tinge. Sexes alike in plumage, male larger than female. Juvenile is patterned much like adult, but top of head and neck pale brown, side of head contrastingly dark brown, only rudimentary off-white napeband, arc over eye pale blue, underbody pale brown (with uppertail-coverts much as adult), and outer greater coverts have paler brown edges and tips, bill black-brown with large pale orange base of lower mandible, gape swollen and pale orange, and iris dull brown. Race *inopinatus* is larger than nominate, and ground colour of upperparts, especially rump, slightly duller citrine-olive, with weaker yellow tinge. Voice. Varies. Most common call in Australia a rapid high-pitched shrill piping "t-tee, t-tee, t-tee..." or "p'pit, p'pit, p'pit..." repeated at short intervals in bursts at even pitch (labelled song); in New Guinea, most common call high-pitched "see-see-see..." (possibly also referring to song). Flight call a sharp "tip", "dip" or mournful "weep"; alarm call a flat hard trill, "si-si-si...". Other calls include harsh rasping "sheep-sheep" or "tserp, tserp" as contact when feeding; soft mewling notes, also said to be for contact when feeding; and single piping whistle.

Habitat. In Australia, mainly open eucalypt forests and woodlands with either grassy or shrubby understorey, and often mixed with paperbarks (*Melaleuca*), *Grevillea*, *Lophostemon* and *Livistona* palms; less often in low riparian eucalypt woodland, e.g. dominated by bloodwoods (*Corymbia*) or river red gum (*Eucalyptus camaldulensis*), with shrubby understorey (often including *Grevillea*), or dense riparian and littoral paperbark forests; often in riparian associations in semi-arid regions, and only occasionally in adjacent dry woodland or savanna. Occasionally in vine scrubs or monsoon forests, though mainly at ecotone between latter and open forest; rarely, in patches of cypress-pines (*Callitris*) or mangrove associations. Sometimes in parks and gardens. In Northern Territory, significantly more abundant in riparian than in non-riparian vegetation; associated with riparian zones in high-rainfall areas, with abundant *Melaleuca* and *Bambusa*, but also occupies riparian zones with much grass cover but little cover of *Pandanus*, *Melaleuca* or rainforest vegetation and relatively distant from rivers. In New Guinea, inhabits savanna woodland, mainly eucalypt-dominated associations, less often those dominated by paperbarks, occasionally extending into rainforest edge; lowlands and foothills, from sea-level mainly to 450 m, but to 800 m on Sogeri Plateau.

Food and Feeding. Invertebrates (mainly insects, also spiders) and nectar (e.g. of *Eucalyptus*, *Melaleuca*, *Grevillea*). Forages at all levels, mainly in outer foliage and at flowers in upper crowns of trees; occasionally on branches or trunks of trees, in shrubs in understorey, and in mistletoe (*Loranthaceae*). Probes flowers for nectar; arthropods usually gleaned from foliage or from flowers when probing for nectar; sometimes hang-gleans or sally-hovers to take food from outer foliage, and seldom sallies in air. Of 90 feeding observations in Kakadu National Park (Northern Territory), 71% involved gleaning, 8% probing, 12% flutter-chasing, and 8% sallying (2% sally-striking in air, 3% sally-striking at hard substrates, 3% sally-hovering). Very active and vocal. Forages singly, in pairs, and in small, loose flocks of up to c. 20 individuals; often with *M. lunatus*, and once seen in mixed feeding flock of c. 100 birds of ten species.

Breeding. Few observations from New Guinea, nestlings mid-Oct and fledglings in Oct and Apr, suggesting breeding in middle to late dry season and towards end of wet season (and possibly bimodal); in Australia, breeding recorded Apr–Oct in N, in all months except Feb (mainly winter to mid-summer) in E, and eggs Jul–Jan in New South Wales. Usually solitary, but some evidence of occasional co-operative breeding. Nest cup-shaped, typically made of bark (usually of paperbark), bound with spider web, sometimes grass also used and, less often, leaves, feathers, spider egg sacs, down or synthetic fibres, external diameter 5.7–6.4 cm, depth 5.1–5.7 cm, internal diameter 4.4–6.4 cm, depth 3.8 cm; usually suspended from thin, sometimes horizontal, fork or among hanging foliage, sometimes in outer branches, in tall tree (often *Eucalyptus* or *Melaleuca*), 1.4–20 m (mean 7.5 m) above ground. Clutch usually 2 eggs; incubation period at least 13 days; chicks fed by both sexes, nestling period at least 14 days; fledglings fed by both parents. Nests parasitized by Pallid (*Cuculus pallidus*) and Brush Cuckoos (*Cacomantis variolosus*).

Movements. Resident; local movements reported near edge of range (which sometimes described as nomadic). Some seasonal patterns in occurrence may result from movements between habitats, e.g. in N Queensland (Cape York Peninsula) said to move from woodland to heathland between seasons. Movements often associated with flowering events.

Status and Conservation. Not globally threatened. Common in Australia. No estimates of total population, but recorded densities range from less than 0.01 birds/ha to 2.1 birds/ha. The only member of genus occurring outside Australia.

150. White-naped Honeyeater

Melithreptus lunatus

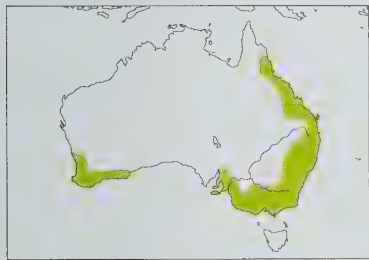

French: M  liphage    lunule **German:** Mondstreif-Honigschmecker **Spanish:** Mielero Nuquiblanco
Other common names: Lunulated/Black-capped Honeyeater; Western White-naped/Western Lunulated Honeyeater (*chloropsis*)

Taxonomy. *Certhia lunata* Vieillot, 1802, Nouvelle Hollande = region of Sydney, New South Wales, Australia.

Closest to *M. albugularis* and *M. affinis*, the three species characterized by tapering white napeband, uniformly citrine dorsum, white breast to vent, slender sepia-toned feet, and black of head extending to side of breast. May form a superspecies with *M. affinis*. Nominata race possibly exhibits clinal variation in size, being slightly larger in S of range. Two subspecies recognized.

Subspecies and Distribution.

M. l. chloropsis Gould, 1848 – SW Western Australia (N to Swan R Plain and Wheatbelt in W).
M. l. lunatus (Vieillot, 1802) – E & SE Australia, from N Queensland (wet tropics) S, extending W to inland slopes of Great Divide and adjacent inland plains, to Victoria and to SE South Australia (including Kangaroo I).

Descriptive notes. 10.5–15.5 cm; male 11.5–25 g and female 11.5–15 g (nominata), two males 15 g and 16 g (*chloropsis*). Nominata race has black cap covering top and side of head and hindneck, arc of bare bright orange-red skin above eye, short white crescent-shaped band across nape; upperbody and uppertail olive-green, tail with brown sides edged with olive; upperwing mostly olive-brown, olive-green tips of coverts and olive-green outer edges of remiges (olive panel on folded wing); chin and throat white, black mark on upper chin; underbody white, dark grey-brown wash on side of breast and flanks, undertail light

brown, underwing white with brown trailing edge and tip; iris brown; bill and gape black; legs brown to black, often tinged orange, especially on feet. Sexes alike in plumage, male larger than female. Juvenile is patterned as adult but much duller overall, top of head and hindneck brown, contrastingly darker black-brown mask, light brown to pale orange arc of bare skin over eye, narrower and diffuse off-white to yellowish-buff napeband, upperparts mostly brown (except for olive-green uppertail-coverts), outer greater coverts, primary coverts and alula initially with narrow olive-buff fringes at tips, underbody off-white, bill dull orange with grey-black distal half of upper mandible (area of black increasing with age), gape swollen and orange. Race *chloropsis* is slightly larger than nominate (with significantly longer bill and tarsus), arc of bare skin over eye chalky white, sometimes faintly tinged pale blue or green-blue (not red). **VOICE.** Sometimes noisy, and during breeding season continual noisy aerial chases. Most common call a half-whistled, half-hissed, churring “sherp-sherp-sherp...” or “tserp-tserp-tserp...”, given frequently throughout day. Other calls include short single note with upward inflection, given often during foraging or in flight; short, high-pitched, rather plaintive insect-like “chip”, “tsip”, “tsit” or “twit”, uttered continually as contact during foraging and while in flight during migration; and “joe-joe-joe”, to advertise territory. Alarm call a tense quiet “pew-pew-pew...” or repeated staccato notes.

Habitat. Mainly open eucalypt forests and woodlands, especially dry sclerophyll forest or woodland, with patchy or moderately well-developed understorey of shrubs such as *Acacia*, *Banksia*, casuarina or heath; also tall wet sclerophyll forest, often with well-developed understorey of *Acacia*, and occasionally dense subcanopy of rainforest. Sometimes in riparian woodland of casuarinas; open or coastal *Banksia* shrubland; heathland with low scattered emergent eucalypts; or alpine herbfields. Found in urban gardens and streets in some areas. Occasionally in plantations of exotic pines.

Food and Feeding. Arthropods (mainly insects, some spiders) and nectar (including of *Eucalyptus*, *Banksia*, *Grevillea*); occasionally manna, honeydew and lerp. In South Australia, estimated ratio of nectar to insects (latter probably including lerp and honeydew) in diet 24:76. Forages at all heights, mainly in canopy, mostly in trees (particularly *Eucalyptus*), less often in shrubs (including *Banksia*, *Grevillea*, *Callistemon*, *Astroloma*) or mistletoe (e.g. *Lysiana*, *Amyema*); searches mainly in foliage, particularly outer foliage, on twigs and flowers in crowns of tall eucalypts, less often on branches or trunks; occasionally on ground. Mean foraging height at site in E Australia 9.6 m (with 79% of observations above 4 m), and at site in W Australia 7.7 m (91% above 5 m). At five sites in E Australia, more than 70% of foraging observations among foliage; in W Australia all foraging in foliage at one site, but at two other sites most foraging on branches and trunks (less than 40% of observations involved foliage). At site in E Australia, two phases of foraging activity, first in early morning, characterized by much nectar-feeding and little foraging for insects, and second during rest of day, with slight increase in rates of insect-eating and corresponding reduction in nectar consumption. Insects taken by gleaning from foliage or probing bark, and occasionally by sallying; probes flowers for nectar with rapid circular motion. Often acrobatic, sometimes standing erect or hanging upside-down. Forages singly, in pairs, or in small loose flocks of twelve or more individuals, but can gather in large numbers in areas with abundant flowering plants; also in flocks of hundreds or even thousands on migration. Often forages with other meliphagids, including *M. brevirostris* and *Lichenostomus chrysops*; can be aggressive to other foliage-gleaners.

Breeding. Recorded in all months, but season mainly late winter to early summer, Aug–Jan (eggs Jul–Jan); usually double brooded. Regularly breeds co-operatively and semi-colonially, but also nests solitary. Nest probably built by female alone, sometimes accompanied by other birds, open and cup-shaped or purse-shaped, sometimes deep, usually woven from grass, bark or spider web, sometimes with feathers, moss, plant down, lichen or leaves matted into structure, lined with plant down, fine grass, rootlets, small leaves, feathers, hair, fur, bark, wool or moss, sometimes unlined, external diameter 5.1–6.4 cm, depth 3.5–7.6 cm, internal diameter 3.8–4.4 cm, depth 3.8–4.4 cm; usually suspended by rim among outer foliage high above ground, sometimes in low branches, usually in tree or sapling (especially *Eucalyptus*) but sometimes in pendulous foliage of mistletoe, 0.2–4.0 m (mean 9.5 m) above ground. Clutch 2–3 eggs, mean 2.67; incubation probably by female only, period usually c. 14 days, once c. 10 days; chicks fed by both sexes, and by auxiliaries if present, nestling period c. 14–16 days. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*). From 24 eggs in ten nests, 0.7 young fledged per nest; of 45 nests at which outcome known, 30 (67%) fledged at least one young.

Movements. Partly migratory and partly sedentary. Over much of range resident, with local movements (often described as locally nomadic), although these populations often subject to some regular seasonal influx and exodus movements, and other areas visited irregularly. Migration apparently confined to populations on and E of Great Divide, from S Queensland or N New South Wales S to Victoria (recorded throughout year in most of this range, and such populations assumed to be at least partly resident), consists of exodus from high altitudes and movement along Great Divide and adjacent slopes and scarps; many birds return to same area year after year. Migrates in monospecific flocks or in flocks with *Lichenostomus chrysops* or, occasionally, *Anthochaera carunculata*; seen on passage in flocks of up to 100 individuals, and thousands may pass over a given point during one day (e.g. hundreds of thousands of honeyeaters, mainly of present species, moving N along coast at Mallacoota, in E Victoria); flocks usually smaller and more dispersed on S passage. On migration, follows valleys and timbered ridges, or lines of trees.

Status and Conservation. Not globally threatened. Common. No estimates of total population but recorded densities of up to 5 birds/ha and, exceptionally, 12.1 birds/ha. In counts along a 200-km transect through C Victoria, mean densities 0.57 birds/ha in summer, 0.57 in autumn, 0.47 in winter, and 0.38 in spring, with maximum recorded density 3.9 birds/ha; at another site in C Victoria maximum 12.1 birds/ha, yet few birds present for ten months of the year in which this density recorded. After experimental removal of *Manorina melanophrys* from sites near Melbourne (S Victoria), present species moved in to vacated sites in order to forage on psyllids. Reports of this species from Kent Group, in Bass Strait, assumed to be referable to misidentified *M. validirostris* or *M. affinis*.

151. Black-headed Honeyeater

Melithreptus affinis

French: M  liphage    t  te noire **Spanish:** Mielero Carinegro
German: Schwarzkopf-Honigschmecker
Other common names: Black-capped/King Island Honeyeater

Taxonomy. *Eidopsarus affinis* Lesson, 1839, Nova Wallia meridionalis = Tasmania.

Closest to *M. albugularis* and *M. lunatus*, the three species characterized by tapering white napeband, uniformly citrine dorsum, white breast to vent, slender sepia-toned feet, and black of head extending to side of breast. May form a superspecies with *M. lunatus*. Birds on King I described as race *alisteri*, but no constant differences apparent between them and populations from mainland Tasmania and Flinders I. Monotypic.

Distribution. Islands in Bass Strait (King I and Furneaux Group), and Tasmania.

Descriptive notes. 14 cm; male 14–17.5 g, female 15.1 g. Small honeyeater with short and only slightly downcurved bill, and rather short tail. Has black hood marked only with arc of bare white or cream skin over eye, and with black of lower neck extending down in thin spur onto side of white breast; lower hindneck olive-brown, upperbody olive-green, brighter on rump and uppertail-coverts, contrasting with olive-brown to greyish-brown uppertail and upperwing (angle of wing slightly darker brown); remiges finely edged pale olive-grey, and wing-coverts fringed pale olive-brown; below, including lower throat, white, with pale

greyish-buff wash on lower underbody; undertail pale grey-brown, underwing pale greyish-buff with broad brown trailing edge and tip; iris blackish-brown; bill and gape grey-black; legs grey to brown. Sexes alike in plumage, male larger than female. Juvenile is similar to adult, but with olive-brown cap and hindneck, rudimentary napeband (a few buff-yellow feathers at side of nape), black-brown mask (lores, ear-coverts, malar area and chin) enclosing blue-tinged arc of bare skin above eye, warm brown upperbody grading to olive on uppertail-coverts, upperwing slightly paler and greyer than adult, much more conspicuous olive fringes on coverts, throat buff-yellow, merging into creamy on underbody, bill grey-black with buff-orange tip, nostrils and base of lower mandible, and buff-orange gape initially swollen. **VOICE.** Noisy. Main vocalization a repeated sharp piping “pee” of 2 or more notes; given throughout year, especially during nest-building period, and often in flight. Other calls include harsh churring “shirp-shirp-shirp...”; soft “chip” said to be given at nest-site.

Habitat. Mostly dry sclerophyll forests dominated by *Eucalyptus* and with sparse to dense understorey of shrubs, heath, sedges or grass, usually preferring areas of denser growth; also regularly in mature wet sclerophyll forest. Less often in open eucalypt woodlands or, very occasionally, subalpine forest, coastal heathlands or low scrubland; rarely, in cool temperate rainforest of antarctic beech (*Nothofagus cunninghamii*), in buttongrass (*Gymnoschoenus sphaerocephalus*) sedgeland with scattered emergent eucalypts, or in cleared treeless areas. Sometimes in parks and gardens. Preference for mature and denser dry and wet forests; in logged areas, usually found where mature trees retained. Mostly below 1000 m; sometimes in alpine and subalpine zones to c. 1200 m.

Food and Feeding. Predominantly arthropods (mainly insects, also spiders); some nectar and fruit. Forages mostly among foliage of saplings or crowns of trees; also among twigs in canopy, on bark of trunks and larger branches of trees or saplings, and sometimes in understorey, herb layer or among leaf litter on ground. Foraged at higher level in breeding season (median height 15 m) than in non-breeding season (11 m). Mostly gleans from foliage, sometimes hanging upside-down, and occasionally from bark of branches; very occasionally feeds at flowers; seldom sallies in air. Usually in twos (more commonly during breeding season, and which probably pairs) or in small flocks

of up to 20 individuals, latter comprising several mated pairs, unattached adults and immatures from previous breeding season. Sometimes with *M. validirostris*.

Breeding. Season late Sept to Feb, mainly Nov–Jan, with eggs recorded Dec. and nestlings Sept–Nov and Feb; usually double-brooded. Loosely colonial, and recorded as breeding co-operatively, but also nests solitarily. Nest built by both sexes, a deep cup, sometimes pointed at base and with thick bulging sides, made usually of bark, sometimes with some grass, twigs, leaves, fibres, wool, hair, moss or lichen, often bound with spider web or silk, lined with feathers, fur, wool or thistle down. external diameter 7–7.6 cm, depth c. 8–8 cm, internal diameter 4.4–5.1 cm, depth 4.4–5.7 cm; usually suspended from horizontal branch or hanging twigs and well concealed among foliage or twigs in crown of tree or sapling (especially *Eucalyptus*), 2.1–30 m (mean 14.1 m) above ground. Clutch usually 3 eggs, re-lays if clutch lost; incubation by both sexes or by female alone, period recorded as less than 21 days and as c. 16 days; chicks fed by both sexes, no information on duration of nestling period; fledglings fed by both parents. Nests parasitized by Pallid (*Cuculus pallidus*) and Fan-tailed Cuckoos (*Cacomantis flabelliformis*) and by Horsfield’s Bronze-cuckoo (*Chrysococcyx basalis*).

Movements. Resident. Some local movements (sometimes described as locally nomadic) by part of population after breeding, in winter, though extent of these not known. Flocks may move irregularly, sometimes appearing at trees that are flowering unseasonally.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tasmania EBA. Common and widespread in Tasmania (except SW); locally common on King I; common and widespread on Flinders I (and probably elsewhere in Furneaux Group). No estimates of total population: recorded densities of up to 1.94 birds/ha. Tends to be significantly more numerous in mature and denser forests (either unburnt or unlogged); in one study in dry sclerophyll forest, density significantly greater in mature forest of 12 years or older than in young regrowth up to 6 years old or old regrowth 6–12 years old; in another study in recently logged forest, mean density higher where more mature trees retained and canopy more continuous than at three sites where few mature trees retained and canopy more open.

Genus *ENTOMYZON* Swainson, 1825

152. Blue-faced Honeyeater

Entomyzon cyanotis

French: Méléphage à oreillons bleus German: Blauohr-Honigfresser Spanish: Mielero Cariatul Other common names: White-quilled Honeyeater

Taxonomy. *Gracula cyanotis* Latham. 1801. Nova Hollandia = Sydney, New South Wales, Australia. Closely allied to *Meliphaga*; allied also to *Manorina*. Race *griseigularis* formerly referred to by name *hartertii*, but holotype of latter (from Cooktown, in N Queensland) is intergrade between S New Guinea/N Australian population and nominate race of E Australia. Proposed race *apsleyi* (Melville I, in Northern Territory) synonymized with *albigensis*. Three subspecies recognized.

Subspecies and Distribution.

E. c. griseigularis van Oort, 1909 – S New Guinea (Trans-Fly and Digoel region, from Merauke E to Wassi Kussa R) and N Australia (Cape York Peninsula, in N Queensland).
E. c. albigensis Gould, 1841 – N Western Australia (Kimberley Division) E across Top End of Northern Territory (including Melville I) to extreme NW Queensland (Nicholson–Leichhardt rivers, on S Gulf of Carpentaria).
E. c. cyanotis (Latham, 1801) – E Australia from base of Cape York Peninsula S (in Queensland E of Thomson–Barcoo Drainage Basin) to NC & NW Victoria (mainly along Murray R and N foothills of Great Divide) and in SE South Australia.

Descriptive notes. 26–32.3 cm; male 80–135 g, female 84–119 g. Distinctive, large, sturdy and full-chested honeyeater with strong, decurved bill, broad rounded wings and moderately long tail. Nominative race has black head, neck and bib, marked with large bright blue bare patch around eye (darker blue on lower rear quarter), narrow white crescent across nape; white malar stripe continues and broadens along side of neck to meet white underbody, and separates black of side of head and neck from bib (which grades from black on chin to grey-black on upper breast); otherwise, mostly golden olive-green above,

uppertail broadly tipped white when fresh (except in centre); upperwing with slightly paler outer webs on inner primaries and bases of outer primaries (diffuse paler panel on folded wing), brown tips on outer primaries (visible on folded wing), brown inner webs of secondaries and inner primaries (visible only in flight), diffuse brown tips on greater primary coverts, small dark patch at bend of folded wing; white below, undertail grey with broad white tip; underwing largely grey (darkest on coverts), basal primaries pink-buff forming rounded patch; iris cream; bill black, pale blue base; legs dark grey. Sexes alike in plumage, male larger than female. Juvenile is similar to adult but duller, with dark areas of head, neck and breast grey (not black), upperparts with olive-brown

tinge, bill brown with cream tip and yellow base and gape, facial skin also yellow (sometimes a small area of blue in front of eye), iris grey-brown to creamy brown, and legs dark blue-grey; immature like adult, but up to 6 months old facial skin mostly yellow with varying areas of green or greenish-yellow, then becoming mostly greenish, and gradually obtaining adult coloration at c. 16 months old. Race *griseigularis* is significantly smaller than nominate but similar in plumage, though pink-buff patch on underwing slightly larger; *albigensis* is similar in size to nominate, but underwing patch white (not pinkish) and larger, conspicuous on both upperwing and underwing in flight, also facial skin more yellowish or greenish, and iris orange-yellow. VOICE. Often noisy; one of first birds to call in morning, and calls throughout day, and often in flight. Main call a repeated, querulous piping “woik” or “queet”, each note rising at end; also as loud “weet! weet! weet!” at day-break. Other calls include harsh squeaks, mewling or scolding; a “hwit hwit” call; and soft chirping during feeding of mate or nestlings.

Habitat. Mostly open forests and woodlands, particularly riparian associations. Mainly dry, open sclerophyll woodlands or forests, including open savanna woodland, typically dominated by *Eucalyptus* (sometimes mixed with *Callitris* or casuarina, but rarely in pure stands of these), with grassy understorey or with secondary layer of smaller trees and a sclerophyllous understorey ranging from sparse to dense and heathy, and with varying grassy ground layer; also commonly in open paperbark (*Melaleuca*) woodland with grassy understorey, and often in riparian woodlands and forests such as riverine forests of river red gum (*Eucalyptus camaldulensis*), sometimes mixed with coolibah (*Eucalyptus coolabah*), or of weeping paperbark (*Melaleuca leucadendra*). Also commonly in mixed woodland dominated by broadleaf species such as *Excoecaria parvifolia* and *Bauhinia*. Regularly in modified habitats, including partly cleared agricultural land or orchards, and commonly in parks, gardens and golf courses of some cities and towns. Sometimes in mixed stands or woodlands of *Pandanus* and eucalypts or grevilleas, or thickets of *Pandanus*, or at edges of patches of monsoon rainforest in N Australia; also sometimes in mangroves, coastal heathlands, low open coastal *Banksia* forest and wet sclerophyll forest; in New Guinea, also in tall scrub. Sea-level to 850 m, rarely to 1000 m.

Food and Feeding. Mainly arthropods (mostly insects, some spiders) and nectar (often of eucalypts), but also fruit (from native and exotic plants); known to take small lizards at times. Forages at flowers (predominantly of *Eucalyptus*, *Melaleuca* or *Grevillea*), on trunks and branches of trees, in foliage (including dead leaves) of trees and shrubs, and aerially; occasionally on ground. Often in palms; in N Australia searches *Pandanus spiralis* for arthropods, choosing these trees over others in area. Probes flowers for nectar; catches arthropods by gleaning and probing, and also by sallying, mostly sally-hovering and sally-striking in air, and by flutter-chasing, in which bird moves rapidly through vegetation in pursuit of disturbed prey. Hangs and clambers about in variety of positions. Sometimes forages around houses or other structures, and from rubbish bins; seen to probe under eaves and from pipes. Active, noisy, gregarious and aggressive, though sometimes described as wary. Usually in small parties (of up to seven individuals), less often singly or in twos (possibly pairs); sometimes in larger groups of up to 30 or so. Often associates loosely with other species, and seen to forage with *Philemon citreogularis*; also chases other species foraging in same tree or nearby.

Breeding. Few records from New Guinea, in Feb and Jun, and probably breeds in wet season and early dry season; in Australia recorded in all months, mainly winter–spring, with most records of eggs, nestlings or fledglings Sept–Nov, and possibly earlier in N Australia (middle to late dry season) than in S; usually two broods. Normally solitary; one observation of possible group nesting and a few records of communal breeding, with up to four attendants. Both adults bring nesting material, nest a neat rounded cup of strips of bark and, less often, leaves, sticks and cocoons, lined with fine bark, grasses, plant down and wool, average external diameter 15.2 cm, depth 17.8 cm, internal diameter 10.2 cm, depth 6.4 cm; sometimes builds large pendulous bark nest (one 54 cm long); material from old nests reused or material stolen from nest of other species, or nest of other taken over; nest supported by sides or base, rarely suspended by rim from fork of branch, usually wedged into fork (especially where bark debris has collected), or built on top of grass-tree (*Xanthorrhoea*) or palm, on palm fronds near main stem, or occasionally on top of stump or post or in hollow spout, site 1.5–15 m (average 6.9 m) above ground; often nests in or on old domed stick nest of Australasian babblers (*Pomatostomus*), entrance to which often enlarged and own nest built inside, or builds nest in depression on top or side of babbler nest; occasionally builds on old nest of other species, including *Philemon corniculatus*, *Philemon argenticeps* and *Philemon citreogularis*, *Manorina melanoccephala*, *Anthochaera carunculata*, and Magpie-lark (*Grallina cyanoleuca*). Clutch 2 eggs, rarely 3 (records of 4–7 eggs in nests thought to involve more than one female); incubation by female only, period 16–17 days; chicks fed by both adults and by any helpers present, nestling period (in captivity, for two young) 23 days and 24 days; both parents and any helpers feed fledglings, which remain with adults for at least several weeks, but fledglings also seen to forage independently when only one day out of nest. Nests parasitized by Common Koel (*Eudynamis scolopacea*) and Pallid Cuckoo (*Cuculus pallidus*).

Movements. Probably resident in New Guinea, where described as locally nomadic. Appears to be largely resident throughout Australian range, especially in N; some local movements, possibly more extensive S of Tropic of Capricorn. No evidence for suggestion that species is migratory. Numbers at specific locations often fluctuate, and only a visitor at some sites, indicating some movement; seasonal occurrence at a few sites and apparent limited movement of small numbers reported from W slopes of Great Divide in S Queensland–N New South Wales, possibly E & NE towards coast. Vagrant or occasional at various sites at edge of normal range, and sometimes well beyond it.

Status and Conservation. Not globally threatened. Common in most of range. No estimates of total population, but recorded densities of 0.02–0.67 birds/ha in Australia. Populations around Logan Reserve, in SE Queensland, said to have declined in mid-1980s but increased again by early 1990s. At least formerly considered a pest in orchards. Early claim of this species’ presence in Aru Is not supported by contemporary sources.

Genus *PHILEMON* Vieillot, 1816

153. Dusky Friarbird

Philemon fuscicapillus

French: Polochion sombre **German:** Morotailederkopf **Spanish:** Filemón Sombrio
Other common names: Morotai Friarbird

Taxonomy. *Tropidorhynchus fuscicapillus* Wallace, 1862, Morty Island = Morotai, north Moluccas. Forms a superspecies with *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli*, *P. eichhorni* and *P. albitorques*. Formerly suggested that all may belong to a single species, or that present species may be conspecific with first three of these. Monotypic.
Distribution. Morotai, Halmahera and, probably, Bacan, in N Moluccas.

Descriptive notes. 30 cm. Large, rather drab honeyeater with moderately long, heavy and gently decurved bill with slight protuberance (casque) at base of bill. Plumage is plain grey-brown above, darker brown on top of head and neck, upperwing faintly tinged olive; large area of pale pink bare skin on lores and broadly around eye (sparsely covered with bristles), dense and hair-like dark blackish-brown malar stripe that merges into similarly coloured ear-coverts, and dull greyish-white chin and throat faintly washed yellow on lower throat; underbody paler grey-brown than upperparts, with faint yellow wash on breast; underwing

grey-brown; iris red; bill black; legs grey-black to black. Sexes alike in plumage, male probably larger than female. Juvenile and immature undescribed. **VOICE.** No details; calls that appear to be made by this species very similar to those of *P. buceroides*.

Habitat. On Halmahera, recent records in primary forest and logged forest, and not recorded in mangroves; in 1945–1950, observed in coconut plantations and secondary growth. Recent records on Halmahera below 120 m and possibly up to 510 m.

Food and Feeding. Little information. Forages in canopy of tall trees; inconspicuous and infrequently observed. Usually seen singly, occasionally in twos (probably pairs); formerly observed in small parties.

Breeding. Male with fairly enlarged gonads in Apr, and two juveniles in May. No other information.

Movements. Probably resident, with some local movements.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Northern Maluku EBA. No estimates of population, but apparently uncommon; very few confirmed recent records and current population thought to be small, although considered widespread and common in 1945. Considered Vulnerable owing to potential or real decline of population from earlier levels, and ongoing loss and degradation of habitat. All recent records are from Halmahera (but no specimen records for this island); 26 museum specimens are from Morotai, all collected before 1950; no definite records for Bacan, and occurrence there needs confirmation. Currently, much forest in N Moluccas still intact, with estimated 89% of total area of Morotai, Halmahera and Bacan still forested at start of 1990s; all forests, however, under increasing threat from continued clearing, particularly in lowlands, for settlements, agricultural crops and plantations, and timber-harvesting; irrigation schemes and mining operations also pose threats.

Bibliography. Anon. (2007a), van Bemmelen (1948), Butchart & Stattersfield (2004), Coates & Bishop (1997), Collier *et al.* (2001), Diamond (1982), Lambert (1994), Poulsen & Lambert (2000), Stattersfield & Capper (2000), White & Bruce (1986).

154. Seram Friarbird

Philemon subcorniculatus

French: Polochion de Céram **German:** Seramlederkopf **Spanish:** Filemón de Seram
Other common names: Grey-necked Friarbird, Grey-necked Honeyeater

Taxonomy. *Merops subcorniculatus* Hombron and Jacquinot, 1841, Seram, Moluccas. Forms a superspecies with *P. fuscicapillus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli*, *P. eichhorni* and *P. albitorques*. Formerly suggested that all may belong to a single species, or that present species may be conspecific with first three of these. Monotypic.
Distribution. Seram, in S Moluccas.

Descriptive notes. 35 cm; four birds 172–223 g. Large to very large honeyeater with rather long, decurved bill with small protuberance at base of upper mandible, and long tail with rather square-cut tip. Plumage is plain olive-brown above with some olive-yellow; large bare patch over lores and broadly around eye varying in colour from blackish-brown to brown or yellowish-brown; narrow dense and hair-like dark brown malar stripe curving up in crescent over rear ear-coverts; slightly elongated and rather shaggy tuft on rear crown, patch of soft silvery grey on hindneck merging into darker grey on lower anterior side of neck bordering

rear ear-coverts; pale brown below, paler than upperparts, with strong yellowish wash on chin, throat and breast; iris brown (possibly varying to red-brown to crimson); bill and casque grey-black; legs greenish-grey or blackish-grey. Sexes alike in plumage, male probably larger than female. Juvenile is much browner and less olive-toned above than adult, with yellow tips on sides of upper back and scapulars (slightly barred effect), grey-brown below, with yellow tips or wash on side of breast, bill

initially more slender and less decurved, without casque. **VOICE.** One of first birds to call in morning, starting before dawn and continuing until sunrise; said to call less often during day. Main call a single explosive “pprow” or “prrrt”, repeated at intervals, and a characteristic sound on Seram; also described as loud “gock” or “geck”. Also single loud, somewhat nasal and rather unmusical notes, repeated at intervals of 2–3 seconds. Small groups sometimes very noisy, with calling and countercalling.

Habitat. Widespread, from lowland mangroves and coconut plantations on coast to primary and disturbed lower montane forests, including forest edge. Sea-level to 1100 m.

Food and Feeding. Poorly known. Seen singly, in twos (possibly pairs) and small groups, mainly in upper levels of forest; noisy and conspicuous.

Breeding. Active nests in Aug (contents unknown). Nest built very high in tall tree. Seen to attack vigorously a pair of Moluccan Red Lories (*Eos bornea*) that was inspecting potential nesting hole in tree; reason for attack not known.

Movements. No data; presumably resident, with local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA. Widespread and very common in Seram; no estimates of population. Recorded at densities of 0–18 birds/ha below 180 m and 0–21 birds/ha above 300 m in unlogged forest, and at 0–24 and 0–16 birds/ha at corresponding elevations in logged forest. Common in Manusela National Park.

Bibliography. Bowler & Taylor (1989a, 1989b, 1993a, 1993b), Coates & Bishop (1997), Diamond (1982), Isherwood *et al.* (1998), Marsden (1998), Stattersfield *et al.* (1998), Stresemann (1914a), Verbeelen (1996), White & Bruce (1986).

155. Black-faced Friarbird

Philemon moluccensis

French: Polochion des Moluques **German:** Burulederkopf **Spanish:** Filemón Moluqueño
Other common names: Buru/Moluccan/Moluccas Friarbird

Taxonomy. *Merops moluccensis* J. F. Gmelin, 1788, Buru, Moluccas. Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. plumigenis*, *P. buceroides*, *P. cockerelli*, *P. eichhorni* and *P. albitorques*. Previously suggested that all may belong to a single species, or that present species may be conspecific with first three of these, or with *P. plumigenis* alone. Monotypic.
Distribution. Buru, in S Moluccas.

Descriptive notes. 31–37 cm. Large to very large honeyeater with long, heavy and slightly decurved bill with no protuberance at base of upper mandible. Plumage is plain grey-brown above, tinged olive when fresh (fading paler and browner with wear), with silvery white to silvery grey side of crown and supercilium (continuing diffusely behind ear-coverts and down side of neck), short silvery tuft on hindneck and side of neck, and large blackish bare patch covering lores and most of side of head; narrow dense and hair-like dark brown malar stripe joining small but sparsely feathered dark brown patch on rear ear-coverts, interrupted by narrow silvery patch on lower anterior ear-coverts; off-white and finely dusky-streaked chin to centre of upper breast (feathers of throat and centre of upper breast slightly lanceolate); rest of underbody pale brown, paler than upperparts, at least sometimes diffusely mottled darker, and becoming paler still on vent and undertail-coverts; underwing pale rufous with darker trailing edge and tip; iris crimson or red; bill black, tinged bluish-black basally; legs bluish-grey to grey-black or black-brown. Sexes alike in plumage, female slightly smaller than male. Juvenile poorly known, differs from adult in having pale yellowish wash or streaking on side of lower throat and side of breast, and narrow greenish-yellow outer edges on remiges (indistinct and diffuse pale panel on folded wing). **VOICE.** Reported as giving wide range of vocalizations; calls thought to be of present species, and not of its visual and vocal mimic the Black-eared Oriole (*Oriolus bournoniensis*), include loud fluid “yio-wheea” and variants, short “ka wha”, and hard “kawah”. Thought to duet.

Habitat. All wooded habitats: lowland and montane primary forest, monsoon forest, secondary forest and woodland, mangroves, heavily disturbed and selectively logged forest, agricultural land and coconut plantations. In recent surveys, found possibly to prefer open areas with some remnant old trees, possibly also at lower altitudes or in valleys; almost certainly more common in logged forest than in primary or secondary forest. Sea-level to 1760 m.

Food and Feeding. Poorly known. Occurs singly and in twos (possibly pairs), mainly in middle to upper levels of habitats; noisy, aggressive and conspicuous.

Breeding. No information.

Movements. No information; presumed resident.

Status and Conservation. Not assessed. Thought not to be globally threatened. Restricted-range species: present in Buru EBA. Conservation status of this species not certain, as frequently treated as conspecific with *P. plumigenis*; the two combined are not globally threatened. Present species is common, with total population estimated at 920,000 individuals. Nevertheless, it is confined to a single island, which could place it at risk in the future.

Bibliography. Coates & Bishop (1997), Diamond (1982), Hartert (1900c), Jepson (1993a), Jones *et al.* (1990), Marsden *et al.* (1997), Poulsen & Lambert (2000), Rheindt & Hutchinson (2007a), Stattersfield *et al.* (1998), Wallace (1863), White & Bruce (1986).

156. Tanimbar Friarbird

Philemon plumigenis

French: Polochion des Tanimbar **German:** Tanimbarlederkopf **Spanish:** Filemón de las Tanimbar

Taxonomy. *Tropidorhynchus plumigenis* G. R. Gray, 1858, Kai Islands, Moluccas. Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. buceroides*, *P. cockerelli*, *P. eichhorni* and *P. albitorques*. Formerly suggested that all may belong to a single species, or that present species may be conspecific with first three of these. Usually treated as race of *P. moluccensis*, but this arrangement inconsistent biogeographically and morphologically with present

On following pages: 157. Helmeted Friarbird (*Philemon buceroides*); 158. New Britain Friarbird (*Philemon cockerelli*); 159. New Ireland Friarbird (*Philemon eichhorni*); 160. White-naped Friarbird (*Philemon albitorques*); 161. Silver-crowned Friarbird (*Philemon argenteiceps*); 162. Noisy Friarbird (*Philemon corniculatus*); 163. New Caledonian Friarbird (*Philemon diemenensis*); 164. Timor Friarbird (*Philemon inornatus*); 165. Brass’s Friarbird (*Philemon brassi*); 166. Little Friarbird (*Philemon citreogularis*); 167. Grey Friarbird (*Philemon kisserensis*); 168. Meyer’s Friarbird (*Philemon meyeri*); 169. White-streaked Friarbird (*Melitograis gilolensis*).

treatment of other taxa within the superspecies, as *P. subcorniculatus* and *P. moluccensis* (of, respectively, Seram and Buru) are more similar to each other than either is to present species. Proposed race *timorlaeensis* (Timorlaut, in Tanimbar Is) considered synonymous with *plumigenis*. Monotypic.

Distribution. Kai Is (Kai Kecil and Kai Besar) and Tanimbar Is (Larat and Yamdena), in E Banda Sea.

Descriptive notes. 31–37 cm. Large to very large honeyeater with long, heavy and slightly decurved bill with slight protuberance at base of upper mandible. Plumage is plain grey-brown above, tinged olive when fresh (fading paler and browner with wear), remiges with olive outer edges, short silvery tuft on hindneck and side of neck; large blackish bare patch covering lores and most of side of head, and narrow dense and hair-like dark brown malar stripe joining small patch on rear ear-coverts; dark brown chin to breast, grey tips on throat feathers, pale yellow streaking or wash on breast; rest of underbody mid-brown, under-

wing pale rufous with darker trailing edge and tip; iris crimson or red; bill black, tinged bluish-black basally; legs grey-black or black-brown. Sexes alike in plumage, male probably larger than female. Juvenile undescribed. Voice. Very vocal. In Kai Is main call a loud, bugling antiphonal duet in which first bird gives loud upslurred “seew”, second bird immediately following with bubbling bugling call lasting c. 1 second, or a series of more musical notes seesawing back and forth and up and down in pitch; one pair appeared to call in duet for c. 25 seconds. Single “seew” and some calls like those of a drongo (*Dicrurus*) also reported.

Habitat. All wooded habitats, including forest and mangroves and also in agricultural land; in Tanimbars, recorded at edge of primary semi-evergreen forest, in secondary woodland and within selectively logged forest. Sea-level to above 250 m on Kai Besar.

Food and Feeding. Poorly known. Occurs singly and in twos (possibly pairs), mainly in middle to upper levels of habitats; noisy, aggressive and conspicuous.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not assessed. Thought not to be globally threatened. Restricted-range species: present in Banda Sea Islands EBA. Conservation status of this species not certain, as frequently treated as a race of *P. moluccensis*; the two combined are not globally threatened. Present species is generally common in Kai Is and Tanimbar Is.

Bibliography. Bishop & Brickell (1999), Coates & Bishop (1997), Diamond (1982), Hartert (1901), Lewis (1993), Rheindt & Hutchinson (2007a), Stattersfield *et al.* (1998), Wallace (1863), White & Bruce (1986).

157. Helmeted Friarbird

Philemon buceroides

French: Polochion casqué **German:** Helmlederkopf **Spanish:** Filemón de Yelmo

Other common names: (Helmeted) Leatherhead, (Little) Friarbird, Monsoon/Mangrove Friarbird; Cape York Friarbird (*yorki*); Melville (Island) Friarbird (*gordoni*); Sandstone Friarbird (*ammitophilus*); Timor (Helmeted) Friarbird (*buceroideis*); New Guinea Friarbird (New Guinea races and *yorki*)

Taxonomy. *Philedon buceroides* Swainson, 1838. “New Holland”; error = Timor.

Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli*, *P. eichhorni* and *P. albitroques*. Formerly suggested that all may belong to a single species. Taxonomy of present species unsettled, and further study required; species as currently constituted may be polyphyletic; limits of races uncertain, and molecular analyses needed, combined with examination of birds at equivalent states of plumage wear, and vocalizations. Races fall into two groups: those from Lesser Sundas (n nominate and *neglectus*) and CN Australia (*gordoni* and *ammitophilus*) form one group, and those of New Guinea and associated islands (*aruensis*, *jobiensis*, *novaeguineae*, *subtuberosus* and *tagulanus*) and NE Australia (*yorki*) form another; groups often treated as two separate species. In N Australia, races *gordoni* and *ammitophilus* occupy different habitats and appear to be allopatric; possibly represent two separate species. Other proposed races are *sumbanus* (from Sumba, in Lesser Sundas) and *plesseni* (Lomblen, in Lesser Sundas), both merged with *neglectus*; *pallidiceps* (Wetar, in Lesser Sundas), synonymized with nominate; *brevipennis* (Utakwa R, in S New Guinea), *fretensis* (Hall Sound, in SE New Guinea) and *trivialis* (Collingwood Bay, on N coast of SE New Guinea), all subsumed in *novaeguineae*; and, in Australia, *confusus* (from Cairns, in N Queensland), treated as synonym of *yorki*. Ten subspecies currently recognized.

Subspecies and Distribution.

P. b. neglectus (Büttikofer, 1891) – Lombok, Sumbawa, Moyo, Sangeang, Komodo, Rinca, Flores, Besar, Adonara, Lomblen, Pantar, Alor and Sumba, in Lesser Sundas.

P. b. buceroides (Swainson, 1838) – Sawu, Roti, Semau, Timor, Atauro and Wetar, in E Lesser Sundas.

P. b. gordoni Mathews, 1912 – N Northern Territory (Tiwi Is and coastal Arnhem Land), in N Australia.

P. b. ammitophilus Schodde *et al.*, 1979 – subcoastal sandstone plateaux of Arnhem Land (S to Katherine Gorge and Mataranka), in Northern Territory.

P. b. novaeguineae (S. Müller, 1843) – West Papuan Is (Waigeo, Kofiau, Salawati, Batanta, Misool), and NW & S New Guinea (Vogelkop E to Geelvink Bay and, in S, E to Milne Bay and, in SE, on N coast E from Kumusi R).

P. b. jobiensis (A. B. Meyer, 1874) – Yapen I (in Geelvink Bay) and N New Guinea from Mamberamo R E to S coastal Huon Gulf (around Salamaua).

P. b. aruensis (A. B. Meyer, 1884) – Aru Is.

P. b. subtuberosus E. J. O. Hartert, 1896 – Trobriand Is (Kaileuna, Kiriwina and Kitava) and D’Entrecasteaux Archipelago (Goodenough, Fergusson and Normanby), off SE New Guinea.

P. b. tagulanus Rothschild & E. J. O. Hartert, 1918 – Tagula I, in Louisiade Archipelago (off SE New Guinea).

P. b. yorki Mathews, 1912 – islands in CW & S Torres Strait, and coastal NE Queensland (S to Weipa, on W Cape York Peninsula, and, in E, to Broad Sound, including some offshore islands), in NE Australia.

Descriptive notes. 32–36 cm; male average 120.6 g and female 107.1 g (nominate), male average 101.2 g and female 90.7 g (*gordoni*), male 100–131 g and female 96–112 g (*ammitophilus*), male 127–179 g and female 120–155 g (*jobiensis*), male 133–146 g and female 98–125 g (*yorki*), 110–145 g (*novaeguineae*). Large to very large honeyeater (the largest on mainland Australia) with heavy and slightly decurved bill, and distinctive backward-sloping and somewhat rounded but varying prominent casque at base of upper mandible. Nominate race is plain grey-brown above and below, with fine white spotting or scaling on rump and uppertail-coverts in fresh plumage; silvery off-white to pale grey-brown top of head and short, upcurled and somewhat “combed” tuft on upper hindneck;

(small bump at base of upper mandible), less developed tuft of feathering on hindneck, brown wash on upperbody, narrow brown tips on secondary and greater primary coverts, indistinct and diffuse greenish-yellow panel on folded wing (narrow edges of secondaries), narrow greenish-yellow edges and fine buff-white tips on rectrices, uniformly off-white chin to upper breast (lacks streaked gorget), slightly duller facial skin, and brownish-red or grey iris; immature like adult but distinctive, casque gradually attains adult shape and size over first year, gorget washed pale yellow, in fresh plumage upperbody and side of breast messily scalloped or barred white (effect reduced with wear), and retains juvenile wing and tail (tips of upperwing-coverts paler, more distinct than in juvenile). Races differ only slightly, mainly in overall size and in size and prominence of casque, probably also subtly in darkness of plumage, “nominate group” tending to have rather pale plumage and “*novaeguineae* group” slightly darker (but plumage markedly affected by wear and fading over year, and examination of range of specimens in equivalent stages of wear required, but such material not available), possibly also in amount and exact distribution of bare skin on head (but available data incomplete); *neglectus* is apparently similar to nominate, but darker overall (and with slightly different vocalizations); *gordoni* has casque small but still obvious; *ammitophilus* has casque very small; *novaeguineae* and *aruensis* have casque well developed; *jobiensis* virtually lacks casque (also, eyes of this race and *novaeguineae* described as sometimes red-brown to brown or grey-brown, but confirmation needed); *subtuberosus* and *tagulanus* have casque of intermediate size; *yorki* has large and prominent casque, pale throat and neck, and silvery crown. Voice. Noisy, with range of rather harsh warbling calls. In New Guinea, heard all day, and often at night, and calling loudest and most frequent in morning; song the most characteristic bird sound of New Guinea and Wallacea lowlands; in Australia, calls most often in early morning or after rain. In New Guinea, song loud and rollicking but monotonous, of phrases of 2–6 (usually 3–4) loud nasal slurs, such as “keeyo-keoway” or “kowee ko keeyo”, repeated up to a dozen times and becoming progressively somewhat louder, pauses of less than 1 second between repetitions. In Wallacea, song described as varying, loud, nasal and coarsely musical 3-note phrases lasting c. 1.5 seconds and repeated at short intervals (race *neglectus*); and a series of 2–3 hoarse, nasal and low-pitched disyllabic “ahga, ahga” phrases lasting 1–2 seconds and repeated at intervals of 10–20 seconds, sometimes monotonously and sometimes with increases in volume; and variant described as “aa, ahga” lasting c. 1 second (nominate race). Other vocalizations include hissing throaty “kurr-rk”, slowly repeated 8–10 times during foraging (bringing no response from mate), and fainter variant sometimes given by bird on nest; mournful and downslurred “poor devil, poor devil”, repeated many times, at regular intervals, by incubating bird, and as location call at dawn and dusk; diagnostic “watch out, watch out”, with stress on first syllable, possibly given only by male; metallic “chilane chilane”, with second syllable stressed and slightly higher than first; and monotonous “chank chank chank”. Other vocalizations reported from New Guinea include repeated single notes, e.g. high-pitched and slurred “quiew” or clear, liquid disyllabic phrase “widow” or disyllabic “wuwu” or “wurri”; also rasping “rrrrrrrr...”. Duetting, both in unison and antiphonally, reported (perhaps most often in late afternoon and early morning, and apparent increase before nesting); at one nest, either member of pair initiated duet, with contribution of one bird at higher pitch; when duet antiphonal, partners together utter phrase, one contributing 2–3 notes, the other 1–2 notes, the two may start or finish together or not.

Habitat. Varies slightly among races in Australia. Race *ammitophilus* mainly on sandstone plateaux and escarpments in sites supporting monsoon forest and broadleaf scrub dominated by *Allosyncarpia ternata*; also in flowering riparian paperbark (*Melaleuca*) forest in valleys, open eucalypt forest or woodlands near escarpments, and ecotone between monsoon forest and open eucalypt forest with flowering *Eucalyptus*, where mostly in near-coastal forests, woodlands and mangroves; *gordoni* occurs coastally, mainly in mangroves, but also in monsoon forests, open eucalypt forests and woodlands with grassy or shrubby understorey, and paperbark swamps, acacia forests, and urban gardens. In Queensland, *yorki* mainly in open forests and woodlands or swamp-forests dominated by eucalypts and paperbarks; also lowland tropical forest, deciduous vine scrubs, mangroves, gallery forest and heathland, and in urban parks and gardens; rarely, at edges of higher-altitude closed forest on tablelands, forests of hoop pine (*Araucaria cunninghamii*) on ridges or in valleys, or stands of casuarinas and *Pandanus* on coral strands. In New Guinea, recorded in all wooded habitats and even scattered tall trees: in mangroves, freshwater swamps, primary rainforest, including riparian vegetation, forest edge, tall secondary growth, open *Eucalyptus* forest and savanna, tall trees in grassland, and modified habitats such as cultivation, plantations (including of teak), gardens, orchards, roadside vegetation and towns, villages and cities. Inhabits undisturbed forest to an altitude of c. 750 m but disturbed habitats up to 1450 m; thought to be recent colonizer of Wau Valley, at 1100 m, and confined to disturbed habitats and forest edge (though one of the numerically dominant birds in valley). In Bintuni Bay, in NW New Guinea, recorded in mangroves and freshwater swamp-forests dominated by *Metroxylon*, *Pandanus* and *Intsia*, in a wide zone of vegetation dominated by the brackish-water palm *Nypa fruticans* lying between these two associations, and in moist lowland rainforests. In examination of vegetation succession (from gardens to forest) resulting from slash-and-burn agriculture in lowland New Guinea, recorded in all except the most recently established garden plots (with much grass cover), and tended to be more abundant in less disturbed plots. In Wallacea, recorded in all wooded habitats, including mangroves, lowland and montane rainforest, semi-evergreen rainforest and monsoon forest, savanna *Eucalyptus* woodland (with grassy understorey) and other open woodlands (e.g. of *Acacia*, *Zizyphus* and *Tamarindus*), swamp-forest, riparian vegetation, coastal scrub, and modified habitats such as agricultural land, plantations of coconuts, candlenuts and bananas, village gardens, and in and around settlements; other habitats include seasonal montane forest dominated by *Eucalyptus urophylla* on Adonara, and closed swamp-forest with diverse range of trees (including *Terminalia*) to 25 m tall on Lomblen; while considered forest-dependent on a range of Wallacean islands, usually recorded in all or most described habitats, with tendency to be more common in forest. In both Wallacea and New Guinea occurs from sea-level to 1600 m, more often in lowlands or mid-montane altitudes to c. 1000 m; in New Guinea locally as high as 2170 m, e.g. 1800 m (Jimi, Kaironk and Simbai Valleys) and 1980 m (Rakamanda, in Enga Province); in Wallacea from sea-level to 1200 m on Lombok, rare above 1000 m on Sumbawa, to 700 m (occasionally 1500 m) on Flores, to above 950 m on Sumba, to 700 m on Timor, to 930 m on Atauro; in Australia mainly coasts and coastal plains, less often adjacent foothills, ranges and tablelands.

Food and Feeding. Mainly nectar, fruit and seeds, also invertebrates (insects, including large mantids and insect larvae, and spiders); rarely, lizards (once, in New Guinea, c. 25 cm in length), and eggs of other birds. Fruits include those of figs (*Ficus*), in New Guinea also of *Psychotria*. Said to feed also on sap exuding from burnt sugar cane. Forages at all levels, mostly in canopy, less often in subcanopy or shrub layer; very occasionally on ground. When in mixed-species flocks, moves quickly through trees, foraging mostly in foliage in or just below upper canopy. Main technique is probing in flowers, of wide variety of trees (e.g. *Schefflera* in Australia and New Guinea, *Sesbania* in Wallacea, also *Metroxylon* in New Guinea), as well as mistletoes (Loranthaceae); also gleans from foliage of inner and outer canopy, from branches and among flowers and fruits, and sallies for insects, including sally-striking for flying insects and sally-hovering at foliage; seen to search for spiders under loose bark. In New Guinea, observed to sally-hover while picking ants (Formicidae) from ant nests, then return to perch to eat them. When feeding on *Syzygium* in New Guinea, moved from one flower cluster to the next by hopping along branches or flying between branches; perched on or beside clusters, and fed on only a few individual flowers before moving to next cluster. Noisy, conspicuous and aggressive, but can be wary. Usually seen singly, in twos (possibly pairs) and in small groups; regularly in parties of up to 20 at sources of abundant food, particularly flowering or fruiting trees, and group of at least 100 individuals once seen in fruiting tree in W New Guinea. Sometimes forage with other species in flowering trees, including *P. argenteiceps*, and one seen in mixed-species feeding flock with ten other species of honeyeater. Pugnacious in defence of food sources and aggressive to smaller bird species in flowering trees, but tolerates its visual mimic the Brown Oriole (*Oriolus szalayi*).

Breeding. Most data from Australia, where breeding recorded in all months except May and Jul, mainly Sept–Feb; on Flores two peaks of laying, in Feb–May and Oct–Dec (only one record in Dec), with few records in Jun (breeding activity declines in Dec–Mar wet season), also nest-building and active nests recorded Aug–Sept on Sumba and nestlings in late Mar on Roti; in New Guinea appears to nest throughout year except early dry season. Nest a large, deep, loosely constructed open cup, made of strips of bark or bark fibre or, less often, sticks, leaves, vine tendrils, sometimes with grass, a few leaves, wool or cobweb added, lined with fine plant stems, fine tendrils and broken leaves; often materials from nests of other species used or material taken from old nests of its own reared; external diameter 15–23 cm, depth 15–18 cm, internal diameter 9–15 cm, depth 8–15 cm; usually suspended from thin fork or in clump of foliage, often also supported, at end of horizontal branch in live tree, particularly *Eucalyptus* or *Melaleuca* (or in mistletoe in these), less often in shrub or mangrove, often close to or over water, 1.5–18 m (mean 7.3 m) above ground; nest of previous year also reused; in New Guinea (few reports) some nests described as pendulous and often in crown of tall tree (2.5–23 m up), also in mangrove; in Australia, apparent nesting association with Spangled Drongo (*Dicrurus bracteatus*), Australasian Figbird (*Sphecotheres vieilloti*) and Metallic Starling (*Aplonis metallica*), possibly for mutual protection (records of up to five figbird nests and a drongo nest in same tree as nest of present species); in New Guinea, twice reported as nesting in same tree as Brown Oriole (nests 8–9 m apart), once in same tree as White-bellied Cuckoo-shrike (*Coracina papuensis*), and reported as nesting in same tree as Hooded (*Cracticus cassicus*) and Black-backed Butcherbirds (*Cracticus mentalis*). In Australia clutch 3–4 eggs, occasionally 5 (mean 3.69 in Queensland), in New Guinea said to be 2–3 eggs (but one brood of four seen); incubation period at two nests 17–19 days; chicks possibly brooded by both parents (confirmation needed), fed by both but at some nests possibly fed only by female, nestling period once more than 15 days in Australia, once c. 17–18 days in New Guinea. Fledglings fed by both parents for at least 2–3 weeks after fledging. Nests parasitized by Common Koel (*Eudynamis scolopacea*) and Pallid Cuckoo (*Cuculus pallidus*).

Movements. Apparently resident throughout much of range, with some local movements (hence claims of nomadism). In Australia, movement from mangroves into Darwin area in autumn–winter, and, in Torres Strait, occasional or regular visitor to some smaller islands. Also appears at sites when *Melaleuca* or *Eucalyptus* in flower. Although described as migratory around L Kutubu, in E New Guinea, moving away during wet season (May to early Sept), extent of such movements not known. **Status and Conservation.** Not globally threatened. In Wallacea, generally widespread and common to abundant, including on Sumbawa, Moyo, Sangeang and Adonara; uncommon on Roti and Atauro. Generally common to abundant in New Guinea; density at Port Moresby 0.53 birds/ha. Locally common to uncommon in Australia; recorded densities of 0.1–5.8 birds/ha at various sites in Northern Territory. In New Guinea, this species is thought to have expanded its range into cultivated mid-mountain valleys only recently; this process continuing. Possible reports of this species on Morotai (off N Halmahera) not confirmed.

158. New Britain Friarbird

Philemon cockerelli

French: Polochion de Nouvelle-Bretagne **Spanish:** Filemón de Nueva Bretaña
German: Cockerell-Lederkopf
Other common names: Bismarck/New Britain Friarbird, New Britain Leatherhead

Taxonomy. *Philemon cockerelli* P. L. Slater, 1877, New Britain.
Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. eichhorni* and *P. albitorques*. Formerly suggested that all may belong to a single species. Treated as a race of *P. buceroides* by some authors. Two subspecies recognized.
Subspecies and Distribution.
P. c. umboi E. J. O. Hartert, 1926 – Umboi, in Bismarck Archipelago.
P. c. cockerelli P. L. Slater, 1877 – New Britain and Duke of York Is, in Bismarck Archipelago.

erets; uppertail narrowly tipped off-white (white reduced or lost with wear), and secondaries and inner primaries have faint and diffuse olive suffusion on outer edges; pale brownish-grey chin and throat bordered below by slightly darker gorget across upper breast, with indistinct dusky mottling or streaking on lower throat to upper breast; rest of underbody very pale grey-brown, undertail brownish-grey; underwing largely whitish, some brownish-grey mottling on coverts, and silvery dark brownish-grey trailing edge and tip; plumage becomes much paler brown with wear; iris dark brown; bill black; legs blue-grey. Sexes alike in plumage, male larger than female. Juvenile is like adult, but wing and tail washed with olive, collar duller, greyish-white, and side of breast brownish-grey with yellowish wash or streaks. Races are very similar: *umboi* differs from nominate only in slightly larger size and heavier bill. **VOICE.** One of noisiest birds on New Britain, vocalizations ranging from rasping sounds to bugle-like notes intermixed with bursts of laughter-like sounds. Can start to call as early as 03:00 hours, often giving monotonous “tok tok tok” until dawn. Song consists of repeated bubbling or rollicking phrases, such as “chowei tow-tow”. Other vocalizations include repeated, disyllabic nasal whistle, “cruu” or “cluu”; harsh “shhiaw”, repeated, sometimes rapidly; hoarse “caw” almost like that of a crow (*Corvus*); and “chong”. Often duets in unison, two birds repeatedly giving same song pattern in synchrony or nearly so.

Habitat. Most wooded habitats, from lowland to mid-montane rainforest, forest edges, tall secondary forest, recently cleared and disturbed areas, coconut plantations, and gardens. Lowlands to c. 1600 m, most commonly in lowlands and hills to c. 1150 m on New Britain and c. 760 m on Umboi; in Nakanai Mts, in W New Britain, seen from c. 1200 m to 1450 m.

Food and Feeding. Diet includes nectar and arthropods. Frequents upper levels of vegetation, mainly canopy. Seen to forage in flowering trees and epiphytes, such as mistletoes (Loranthaceae), probably for nectar; also takes insects by gleaning and, occasionally, by sallying. Noisy and conspicuous. Usually singly or in twos (probably pairs), sometimes in small flocks of up to seven individuals; in Nakanai Mts, one associated with mixed-species flock.

Breeding. Appears to breed in late dry season to wet season on N coast and in middle of dry season on S coast: eggs recorded late Sept to early Feb, active nests Feb and mid-Oct, nest-building mid-Apr and fledged young early Jul. Nest a substantial cup made of dry stems of vines and grass, lined with dry strips of palm frond, exterior sometimes covered with green thick-leaved vines, suspended between strong branches and possibly in fork of branch, concealed by foliage, usually more than 10 m above ground in tree. No information on clutch size, nor on incubation and nesting periods.

Movements. No information. Probably resident, with some local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. Common to abundant in lowlands of New Britain, but less common in mountains. No estimates of global population.

Bibliography. Ap-Thomas & Ap-Thomas (1977), Beehler (1978b), Bishop & Jones (2001), Coates (1990), Coates & Peckover (2001), Diamond (1972b), Eastwood (1995b), Eastwood *et al.* (1997), Finch & McKean (1987), Fletcher (2000a), Gilliard & LeCroy (1967b), Hartert (1926b), LeCroy & Peckover (1983), Mayr & Diamond (2001), Orenstein (1976), Schönwetter & Meise (1981), Stattersfield *et al.* (1998), Storer & Eastwood (1991).

159. New Ireland Friarbird

Philemon eichhorni

French: Polochion de Nouvelle-Irlande **Spanish:** Filemón de Nueva Irlanda
German: Eichhornlederkopf
Other common names: Eichhorn's/Helmeted(!) Friarbird

Taxonomy. *Philemon eichhorni* Rothschild and E. J. O. Hartert, 1924, hills of south-west New Ireland, Bismarck Archipelago.

Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli* and *P. albitorques*. Formerly suggested that all may belong to a single species. Monotypic.

Distribution. New Ireland, in N Bismarck Archipelago.

small blackish bare patch covering lores, area around eye and anterior malar area; tail tipped white, more broadly at outer corners; chin and throat silvery white, finely dark-streaked; underbody pale brown, much paler than upperparts, with greyish-white spotting or scaling (except on belly), undertail brown with greyish-white tip; iris light brown to dark brown; bill black; legs greyish-blue to blue-grey or slate-grey. Sexes alike, male probably larger than female. Juvenile is like adult, but pale edges on some feathers of upperparts giving variably scaly appearance, and throat washed with yellow. **VOICE.** Typical song a 3-note whistled “pu-du-leet”, each note increasing in pitch. No other information. **Habitat.** Montane forest, from 750 m to at least 2200 m; also said to disappear below 900 m.

Food and Feeding. No information.

Breeding. No information.

Movements. Considered resident.

Descriptive notes. 33–35 cm; male 139–147 g, two females 153 g and 177 g. Large, rather drab honeyeater, with long neck, and fairly long, heavy and gently decurved bill (with no protuberance at base of upper mandible). Plumage is plain dull dark brown above, with strongly contrasting, prominent and somewhat fluffy silvery grey collar on hindneck and side of neck meeting pale brownish-grey chin and throat; large dark grey to blackish-brown bare patch covering lores and most of side of head, and narrow dense and hair-like dark brown to blackish malar stripe running below bare facial patch and continuing onto rear ear-coverts; uppertail narrowly tipped off-white (white reduced or lost with wear), and secondaries and inner primaries have faint and diffuse olive suffusion on outer edges; pale brownish-grey chin and throat bordered below by slightly darker gorget across upper breast, with indistinct dusky mottling or streaking on lower throat to upper breast; rest of underbody very pale grey-brown, undertail brownish-grey; underwing largely whitish, some brownish-grey mottling on coverts, and silvery dark brownish-grey trailing edge and tip; plumage becomes much paler brown with wear; iris dark brown; bill black; legs blue-grey. Sexes alike in plumage, male larger than female. Juvenile is like adult, but wing and tail washed with olive, collar duller, greyish-white, and side of breast brownish-grey with yellowish wash or streaks. Races are very similar: *umboi* differs from nominate only in slightly larger size and heavier bill. **VOICE.** One of noisiest birds on New Britain, vocalizations ranging from rasping sounds to bugle-like notes intermixed with bursts of laughter-like sounds. 159. New Ireland Friarbird

Philemon eichhorni

French: Polochion de Nouvelle-Irlande **Spanish:** Filemón de Nueva Irlanda
German: Eichhornlederkopf
Other common names: Eichhorn's/Helmeted(!) Friarbird

Taxonomy. *Philemon eichhorni* Rothschild and E. J. O. Hartert, 1924, hills of south-west New Ireland, Bismarck Archipelago.

Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli* and *P. albitorques*. Formerly suggested that all may belong to a single species. Monotypic.

Distribution. New Ireland, in N Bismarck Archipelago.

Descriptive notes. 32 cm; 82–116 g. Large, dark honeyeater with long, rather heavy and decurved bill (with no protuberance at base of upper mandible). Plumage is plain dark brown to blackish-brown above, with silvery white forehead speckled with black, grading into fine silver and dark streaks on crown, supercilium (curving down behind eye) and rear malar area; dark brown nape and rear ear-coverts continuous with narrow dense and hair-like dark brown malar stripe extending from bill; strongly contrasting and prominent collar of silvery grey and slightly upcurled feathers on hindneck, grading into blackish and silvery white mottled side of neck;

Status and Conservation. Not globally threatened. Restricted-range species: present in New Britain and New Ireland EBA. No estimates of global population; considered common within preferred altitudinal range. Very poorly known species.

Bibliography. Beehler (1978b), Beehler & Alonso (2001), Coates (1990), Coates & Peckover (2001), Hartert (1925), Mayr & Diamond (2001).

160. White-naped Friarbird
Philemon albitorques

French: Polochion à nuque blanche **German:** Manuslederkopf **Spanish:** Filemón Nuquiblanco
Other common names: Admiralty (Island)/Manus Friarbird

Taxonomy. *Philemon albitorques* P. L. Selater, 1877, Admiralty Islands, Bismarck Archipelago. Forms a superspecies with *P. fuscicapillus*, *P. subcorniculatus*, *P. moluccensis*, *P. plumigenis*, *P. buceroides*, *P. cockerelli* and *P. eichhorni*. Formerly suggested that all may belong to a single species. Monotypic.

Distribution. Manus, in Admiralty Is. in N Bismarck Archipelago.

Descriptive notes. 34–37 cm. Large to very large, rather neat and clean-looking honeyeater with medium-length, heavy and slightly decurved bill with only small protuberance at base of upper mandible. Plumage is distinctive, rich brown above, slightly darker on wing and tail and slightly richer chestnut-brown and finely streaked blackish on top of head, with conspicuous white and rather downy collar on hindneck and side of neck, continuous with white of chin and throat; large mostly blackish bare patch covering lores and area around eye, merging to more pinkish-black on anterior lores at base of bill; narrow dense and hair-like dark brown malar stripe ending on rear ear-coverts; white to off-white below, with varying faint buff wash on flanks and upper breast, feathering on throat sparse (sometimes exposing pinkish skin beneath); underwing buff with dark trailing edge and tip; iris dark brown; bill black, pinkish tinge at base of lower mandible, gape dull brownish-orange; legs blue-grey. Sexes alike, male probably larger than female. Juvenile undescribed. **VOICE.** Song characteristic, heard often, a repeated rollicking phrase of 2–5 loud and rapid notes, “chick-ou cou”, “cou, cou” or “tchau-kaka”, the first 2–3 notes descending in pitch, the rest on similar pitch. Most common call described as loud “chauka” from single bird or “chaukapowe” by birds apparently disputing territories. Also loud screech like that of a parrot (Psittacidae); loud fowl-like cacklings; and quieter single harsh nasal notes. Duetting noted, first bird uttering a “chook ook” phrase, other a harsh “arrrrk”, and finished by a frenzied “choong” from first bird.

Habitat. Abundant in all disturbed habitats, including forest edge, town gardens and around villages, and other human habitation; less common in secondary forest and mangroves, and uncommon in other closed forests. Lowlands.

Food and Feeding. Takes nectar from flowering trees; presumed also to eat invertebrates. Noisy, active and conspicuous. Usually seen singly or in twos (probably pairs) or small groups; pugnacious, and highly aggressive in defence of flowering trees.

Breeding. Active nests recorded mid-Mar, early Aug and early Nov, and nest being built in mid-Jul. Nest a bulky cup made of plant material, usually placed moderately high in outer fork of slender branch; one described as flask-shaped, suspended from branch overhanging river and close to active nest of Variable Goshawk (*Accipiter novaehollandiae*); another basket-shaped, in outer fork of branch 5 m above ground. No other information.

Movements. Probably resident, with local movements. Birds seen on Patamu, a small islet c. 500 m off Manus.

Status and Conservation. Not globally threatened. Restricted-range species: present in Admiralty Islands EBA. Common to very common within tiny global range. Suggested that population may have increased greatly in association with human colonization, settlement and clearing on Manus, and that this increase detrimental to Manus Fantail (*Rhipidura semirubra*), which now considered Vulnerable.

161. Silver-crowned Friarbird
Philemon argenteiceps

French: Polochion couronné **German:** Weißscheitel-Lederkopf **Spanish:** Filemón Coronado

Taxonomy. *Tropidorhynchus argenteiceps* Gould, 1840, between King Sound and Port King George IV, Kimberley Division, Western Australia. Nominative race varies clinally in both size and colour, becoming slightly larger from N to S and darker from arid areas to more humid ones. In Northern Territory, proposed races *melvillensis* (from Melville I) and *alexis* (from Alexandria) represent such clinal variation, and both are merged with nominate. Two subspecies recognized.

Subspecies and Distribution.
P. a. argenteiceps (Gould, 1840) – N Western Australia (Kimberley Division, mainly N & E of Fitzroy R, including many offshore islands) E through Top End of Northern Territory (S to upper reaches of drainage basins of Victoria, Roper, McArthur and Nicholson rivers, and on many offshore islands, including Melville I, Groote Eylandt and Sir Edward Pellew Group) to NW Queensland (SE head of Gulf of Carpentaria and N Selwyn Range).

P. a. kempi Mathews, 1912 – Cape York Peninsula (S to E of line from Weipa to Innisfail), in NE Queensland.

Descriptive notes. 25–32 cm; male 70–106 g and female 59–88.5 g (nominate), three males 90–97 g (*kempi*). Medium-sized tropical friarbird with robust, gently decurved bill and large, rounded and laterally compressed casque near base of upper mandible. Nominative race is pale brown-grey above, with silvery white forehead, crown and nape, and short tuft of dark-based silvery feathers on hindneck and side of neck (typically appearing as if combed or ruffled); black bare patch on lores and most of side of head tapers to a point on side of nape; chin to upper breast silvery white, gorget of lanceolate and finely dark-streaked feathers on lower throat and upper breast; lower breast and anterior flanks pale brownish-grey, grading to light grey or whitish on rest of underbody; undertail and underwing brown-grey; iris red-brown, red or crimson; bill and casque black; legs grey-black to black. Sexes alike in plumage, male larger than female. Juvenile has only rudimentary casque (appears as slight

kempi is like nominate, but with significantly smaller casque and slightly smaller bill. **VOICE.** Very noisy, calls and song described as harsh and discordant warbles, squawks and guttural croaking; one of first species to call in dawn chorus, and groups in flowering trees almost deafening at times. Diagnostic song consists of harsh repeated phrases, described as “more tobacco, uh, more tobacco, uh”; apparently given only by male, but female interrupts at a fixed point of song with a disyllabic call. Both members of pair utter deep guttural “grok, grok” during nest-building.

Habitat. Mostly open tropical *Eucalyptus* forests and woodlands, sometimes also with paperbarks (*Melaleuca*) and *Grevillea*, and usually with grassy ground layer but sometimes with shrubby understorey or, on sandstone plateaux, with figs (*Ficus*) in understorey; often in riverine or other riparian woodlands or forests of paperbarks, sometimes with eucalypts co-dominant, and acacias and *Pandanus* in understorey. Sometimes in mixed woodlands of combinations of *Excoecaria*, *Bauhinia*, *Eucalyptus*, *Grevillea*, *Terminalia*, *Atalaya* and boabs (*Adansonia*), with grassy understorey and scattered shrubs; also *Acacia* forest, monsoon forest and mangroves. Often in urban parks and gardens. Mainly in coastal and subcoastal zones and adjacent ranges and plateaux, occasionally extending inland into semi-arid and arid zones.

Food and Feeding. Mainly nectar, from wide variety of plants; also invertebrates (insects, spiders), as well as fruit (especially figs) and some seeds. Forages at all heights, from canopy down to lower strata close to ground, in trees and shrubs. Searches mainly at flowers, particularly of *Eucalyptus* and mistletoes (Loranthaceae), less often on others (e.g. *Grevillea*, *Melaleuca*, *Banksia* and *Lophostemon*), on inner and outer foliage (including dead leaves) of trees, trunks and large branches, foliage and branches of shrubs, and in air. In Kakadu National Park, in Northern Territory, tended to forage at higher levels in vegetation in wet season compared with dry season, and proportional use of substrates also differed seasonally. Obtains nectar by probing flowers. Collects invertebrates by gleaning, probing and sallying, including sally-striking in air and from foliage, branches and trunks, sally-hovering to snatch prey from foliage, and flutter-chasing. Active, sometimes hanging upside-down to reach flowers. Gregarious, usually in small flocks of 4–25 or more individuals, or in twos (probably pairs); rarely seen singly. Gathers at sources of abundant food, such as flowering trees; sometimes forages in loose association with other species, especially other honeyeaters and lorikeets (Psittacidae), and often seen with *P. citreogularis*; large mixed-species flocks in NE Australia.

Breeding. Season Sept–Mar, rarely Jul (nominate); peak around Darwin (Northern Territory) in Sept, after peak of nectar production in woodlands of region, suggesting that other food such as large insects perhaps important for breeding. Female gathers material and builds, sometimes accompanied by male (single report of two birds building); nest a deep, though often thin-walled, bowl made of strips of bark and bark fibre and spider web, sometimes dry grasses, vine tendrils and plant fibre, lined with coarse grass, external diameter 12.7–13 cm, depth 9.7–17.8 cm, suspended firmly by rim in thick horizontal fork, usually high in tree, among dense outer foliage toward end of horizontal or drooping limb, 2.8–15 m (mean 6.9 m) above ground. Clutch usually 2–3 eggs, probably mostly 2; incubation by female, from second egg in 2-egg clutches, period 16 days; chicks fed and tended by both adults, female usually doing more of the work, no information on duration of nestling period. Nests parasitized by Common Koel (*Eudynamis scolopacea*).

Movements. Apparently resident, or partly so, combined with at least local movements. While widely described as nomadic or dispersive, true extent of movements not known. Possibly partly migratory in some regions, e.g. more common Sept–Jan around Mt Isa (Queensland), and, at least formerly, almost entirely absent from Larrimah area (Northern Territory) during dry season. Vagrant at some sites at edge of usual range (e.g. farther S in NE Queensland), over wide span of months. Movements often correlated with flowering of food trees, and seasonal flowering can result in seasonal occurrences.

Status and Conservation. Not globally threatened. Common. No estimates of total population. At various sites in Northern Territory, recorded densities of 0.05–3.93 birds/ha. Range in NE Australia may be contracting.

162. Noisy Friarbird
Philemon corniculatus

French: Polochion criard **German:** Lärnlederkopf **Spanish:** Filemón Chillón
Other common names: (Bald) Friarbird

Taxonomy. *Merops corniculatus* Latham, 1790, Nova Hollandia = Endeavour River, Queensland, north-east Australia.

Forms a superspecies with *P. diemenensis*. Proposed race *elliotti* (from Watson River, in N Queensland) is based on an intergrade between nominate and *monachus*; *clamans*, described from Wallaroo Gorge (Carnarvon Range, in SE Queensland), is synonymized with *monachus*. Two subspecies recognized.

Subspecies and Distribution.
P. c. corniculatus (Latham, 1790) – S New Guinea (Wassi Kussa R E to Oriomo R) and NE Australia (NE Queensland from about Weipa–Iron Range S, extending inland to middle reaches of Mitchell R and Staaten R and upper Norman R, to Mackay).
P. c. monachus (Latham, 1801) – E & SE Australia from CE Queensland (Mackay region) S, extending inland to c. 144–145° E, to CS Victoria (Gippsland).

Descriptive notes. 30–35 cm; male 88–136 g and female 85–103 g (*monachus*), male 87–93 g and two females 87 g and 94 g (nominate). Large friarbird, adult with mostly bare head, and sturdy and gently decurved bill with prominent upright casque at base of upper mandible. Nominate race is dark grey-brown above, with narrow white tip of tail, and mostly bare dull black head and neck with narrow light brown to cream supercilium, and very sparse and fine blackish feathering on lores and anterior malar area; often a dense patch of dark brown feathers in centre of nape and ruff of light grey-brown fluffy feathering on lower hindneck (both areas can

be bare, as most of rest of head); brown-feathered chin merges to off-white and finely brown-streaked upper throat, and has prominent silvery white and finely dark-streaked gorget of long, curving lanceolate feathers across lower throat and centre of upper breast; rest of breast and anterior flanks brown-grey, merging to off-white on rest of underbody; undertail brown-grey, white tip and narrow white inner edges of outer rectrices; underwing brown-grey with white scaling on coverts; iris red, varying from crimson to red-brown (appears to change to red with stress, and cannot be used reliably as age character); bill and triangular casque at base black; legs black-brown or black. Sexes alike in plumage, but male on average slightly larger than female. Juvenile has only rudimentary casque (a small bump at base of upper mandible), is browner above than adult, with more extensive (but still sparse) dark feathering on head and neck, large ruff of fluffy brown to grey-brown feathering on nape, darker brown supercilium, duller buff-white tail tip, indistinct brown tips on upwearing-coverts, narrow white tips on primaries, throat washed lemon-yellow (no obvious gorget, feathers not lanceolate), underbody slightly paler overall, iris greyish, and legs grey-black; immature similar to adult, but casque smaller, upperbody boldly but coarsely scalloped white, gorget washed pale yellow, side of breast and flanks coarsely barred pale yellow to off-white, also retain most of juvenile wing and tail, with brown tips on wing-coverts, white tips on primaries and duller tail tip. Race *monachus* is greyer, less brown, above and slightly darker below than nominate, and has significantly longer wing and tail. **VOICE.** Can be very noisy, almost deafening when in large numbers; considered one of noisiest birds in savanna of S New Guinea. Wide variety of typically loud, harsh and discordant vocalizations, though song can be more melodic. Song given often, but varies, e.g. “chokka-lock” or “four o’clock”, first note (“chokka”) sounding disyllabic owing to inflection, and sometimes seemingly followed by bill-clacks, songs also described as repeated, rolling “ya-kob” or “ch-will”; repeated “yodel chuck” while advancing slowly towards nearby conspecific probably also song. Often duets, described as antiphonal but some may be given in unison (but with birds starting and finishing independently). Song by male to defend nest-site or attract a female; and sings when defending feeding territories, often in duets, in response to intruders. When foraging, utters “chok”, “chup” or “weep” note. Alarm and threat calls appear to vary: described as babbling and querulous notes of varying pitch, loud cries, and possibly “kow-kow-kow”; alarm calls given when mobbing predators or potential predators, e.g. Square-tailed Kite (*Lophoictinia isura*). Other calls (perhaps different renditions of previous ones) include in Australia “chok-chok”, “tobacco, tobacco” and garrulous chattering, in New Guinea also single high nasal note and scolds birds of prey when pursuing them. Geographical variation in some calls seems likely. Bill-clacking or bill-snapping may form part of calls.

Habitat. Wide range of habitats in Australia, most commonly in dry sclerophyll forests and woodlands, usually dominated by *Eucalyptus* and with understorey varying from sparse with grassy ground cover to dense shrub or heath; often in forests of box or ironbark eucalypts, or riparian associations of river red gum (*Eucalyptus camaldulensis*), black box (*Eucalyptus largiflorens*) or coolibah (*Eucalyptus coolabah*). Also mixed forests or woodlands of combinations of *Eucalyptus*, *Angophora*, *Corymbia*, cypress-pine (*Callitris*) or *Acacia* including brigalow (*Acacia harpophylla*), gidgee (*Acacia cambagei*) or mulga (*Acacia aneura*); sometimes in *Acacia* woodland or open shrublands (e.g. of gidgee, mulga, brigalow or combinations of these), including those with understorey of dense emu-bush (*Eremophila*), but can be rare in pure or dominant stands of other non-eucalypt species (e.g. *Callitris*). Sometimes in mallee eucalypt shrubland. Usually found in healthier forest and woodland associations, rather than those affected by dieback, although can be common in small remnant patches and fragmented forests and woodlands. In coastal areas, sometimes in coastal scrub or low forest dominated by *Banksia* or mixed with *Eucalyptus* or *Leptospermum*, low coastal woodland dominated by casuarinas, coastal heathland or mangroves; and coastally and inland, occasionally in riparian associations of paperbarks (*Melaleuca*), casuarinas or bottlebrushes (*Callistemon*), or ecotone between riverine associations and eucalypt woodlands. Only occasionally in wet sclerophyll forest or rainforest. Often in urban areas, in parks and gardens, and along streets, especially with native vegetation in flower; or in vineyards and orchards. In New Guinea common in low, mainly coastal open *Eucalyptus* savanna; in Morehead area found in all habitats.

Food and Feeding. Nectar, pollen, arthropods (mainly insects, also spiders), fruit, and lerp and manna; reported also as taking eggs and nestlings of Common Starling (*Sturnus vulgaris*), and small fish (3 cm long). Forages mainly in crowns of trees, particularly among flowers and foliage of upper canopy, but recorded at all levels, occasionally in understorey or on ground, and in air; also searches on branches and trunks. Probes flowers for nectar, and catches invertebrates by probing, gleaning and sallying, including sally-striking, e.g. for flying termites (Isoptera). In Australia, seen to probe scars on *Eucalyptus*, presumably taking sap from feeding sites of sugar gliders (*Petaurus breviceps*). Wide gape enables it to feed on large cicadas (Cicadoidea), a favourite food during spring–summer (availability of which may limit breeding success). Seen singly, in twos (probably pairs) and in flocks of up to 30 individuals; often forages in loose flocks of 10–20 birds, and sometimes congregates in larger numbers in fruiting or flowering trees; seen also to forage with other species, including *P. citreogularis* and other meliphagids; sometimes frequent aggression between friarbirds and *Anthochaera* wattlebirds in flowering trees, though can forage with little aggression.

Breeding. Few data for New Guinea, recently fledged young Dec; in Australia breeds Aug–Mar, in NE Queensland clutches Aug–Dec, in New South Wales–Victoria clutches Aug–Jan, near Armidale (N New South Wales) laying early Nov to Jan, and at Moruya (SE New South Wales) laying starts late Oct to early Nov (replacements until mid-Dec); occasionally two broods in a season. Female does all or most of building, nest a large, deep, sturdy and open cup or basket usually of long interwoven strips of bark, bark fibre or grass, sometimes wool, bound with spider web or spider egg sacs, lined with fine dry grass, plant stems or sometimes leaves or rootlets (some nests solely of bark); others include thin sticks, twigs, feathers, leaves or pine or casuarina needles, plant fibre or down, lichen, hair, fur or artificial fibres), external diameter 12–17.8 cm, depth 7.6–14 cm, internal diameter 9.5–14 cm, depth 5.1–10 cm; usually suspended from fork (usually horizontal), drooping twigs or foliage, sometimes partly supported, towards outer edge in wide variety of trees and shrubs, including mistletoe (Loranthaceae), 1.8–35 m (mean 9.1 m) up; nest often near those of conspecifics or other species, e.g. Willie Wagtail (*Rhipidura leucophrys*) and Magpie-lark (*Grallina cyanoleuca*); strong nesting association with Leaden Flycatcher (*Myiagra rubecula*), other flycatchers and other species that apparently nest near friarbirds for protection from potential predators. Clutch 2–4

eggs, occasionally 5, most often 3 (mean throughout range 3), clutch size possibly decreases from S to N; incubation by female, period 15–19 days; chicks tended and fed by both sexes, nestling period 16–19 days; family members initially stay together near nest, fledglings fed by both parents for up to 35 days after leaving nest. Nests parasitized by Common Koel (*Eudynamis scolopacea*), Pallid Cuckoo (*Cuculus pallidus*) and possibly Fan-tailed Cuckoo (*Cacomantis flabelliformis*). From 79 eggs in 30 nests at which outcome known, overall success 1.37 fledged young per nest; near Armidale success variable from year to year, of 242 nests over eight seasons 40.9% fledged at least one young and successful nests produced mean of 2.08 fledglings.

Movements. Complex. Patterns of movements appear to differ between races, though for both often appear associated with (or said to be dependent on) flowering of foodplants, especially myrtaceous (e.g. *Angophora*, *Eucalyptus*) and proteaceous (*Banksia*, *Grevillea*) species. Race *monachus* partly migratory, but at many sites throughout range also present all year and considered resident (most of population S of 35° S migratory, and at least part of populations N to SE Queensland also moves); migratory populations move N (to as far as CE Queensland) in autumn–winter and return S in late winter–spring, with strong evidence for a movement along large parts of E coast; near Armidale, where migratory, site-fidelity over many seasons high, but fidelity to natal site appears low. Also, some evidence of altitudinal migration from highlands of SE in autumn–winter. Nominate race in New Guinea and NE Australia poorly known, but apparently largely sedentary, possibly with some coastal movement in dry season. At some sites, throughout range, occurs erratically or numbers vary greatly and thus claimed to be nomadic, but such suggestions appear to reflect lack of knowledge of movements, which probably very local. Coastal influxes in Queensland sometimes coincide with drought inland. Vagrants recorded far beyond normal range, e.g. Lord Howe I.

Status and Conservation. Not globally threatened. In New Guinea, generally fairly common to very common and locally abundant; common in Australia. No estimates of total abundance, but recorded densities of up to 5.4 birds/ha at various sites; much higher densities, of 29 birds/ha, in flowering mugga ironbark (*Eucalyptus sideroxylon*) forest, and up to 44 birds/ha in heavily flowering white box (*Eucalyptus albens*) woodland.

163. New Caledonian Friarbird

Philemon diemenensis

French: Polochion moine **German:** Lessonlederkopf **Spanish:** Filemón de Nueva Caledonia

Taxonomy. *Tropidorhynchus diemenensis* Lesson, 1831, “La Terre de Diémen”; error = New Caledonia. Forms a superspecies with *P. corniculatus*. Monotypic.

Distribution. New Caledonia and Loyalty Is (Lifou and Maré).

Descriptive notes. 27–32 cm; male 69.5–84 g, female 53–62 g. Large honeyeater with moderately long, heavy and slightly decurved bill (no protuberance at base). Head and neck are largely brown, streaked darker brown and grey on forehead, crown and nape, and paler on chin and throat, with silvery grey hindneck-collar, small patch of silvery grey on lower rear ear-coverts, and narrow moustachial stripe of small dark brown feathers; mantle and back brown, merging to dark olive-brown on scapulars, rump and uppertail-coverts (mantle feathers soft and loosely textured, and can be puffed up); uppertail black-brown, with broad and diffuse

slaty blue-grey outer edges when fresh (fairly rapidly lost with wear and fading); upwearing black-brown, conspicuous slaty blue-grey fringes on median coverts, slaty blue-grey outer edges on greater coverts and all except outer couple of remiges (blue-grey margins combining to form conspicuous pale panel and striping on folded wing; blue-grey much reduced with wear and fading); light grey-brown to buff-brown below, with conspicuous buff-white to silvery white and finely black-streaked gorget of long, curving pointed feathers over throat and centre of upper breast; undertail black-brown (reflective, appearing pale brownish-grey in some lights); underwing pale brownish-grey, sparsely mottled white on coverts; iris red-brown to light brown; bill black; legs blue-grey to dark grey-brown. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult but paler and more washed out, and lacking specialized silvery white feathers of throat and breast. **VOICE.** Heard often. Variety of loud squeaks and disjointed notes. Several calls described: a descending whistle; a harsh grating sound while pursuing another bird; and a loud “hee-haw”. Usual call sounds like “popinjay”, last syllable emphasized. Local name “Koniyou” derived from one of its calls.

Habitat. Common in forests, but mainly in open habitats and often forages in gardens around human dwellings; also occurs in other disturbed areas.

Food and Feeding. Insects, nectar and fruit. Probes flowers for nectar, and seen to sally for insects over water; one chased a cicada (Cicadidae) with aerobic manoeuvres and, having captured it, returned to perch and battered the insect before ingesting it. Bold, active and pugnacious, often chasing conspecifics and other birds, including raptors, crows (*Corvus*) and parrots (Psittacidae).

Breeding. Active nests Oct–Dec and juveniles seen Dec. Nest a thick-walled woven cup, made of twigs and leaves, unlined, external diameter 12–13 cm, internal diameter 8.5–9 cm, suspended from small branches high in tree. Clutch 2 eggs; no information on incubation and nestling periods.

Movements. Probably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in New Caledonia EBA. Common in New Caledonia; scarce or uncommon on Lifou. No estimates of global population.

Bibliography. Delacour (1966), Doughty *et al.* (1999), Hannecart & Lécroart (1980), Layard & Layard (1880), Mayr (1940, 1945b), Myers (2004), Ross (1988), Stattersfield *et al.* (1998), Stokes (1980), Tristram (1879).

164. Timor Friarbird

Philemon inornatus

French: Polochion sobre **German:** Timorlederkopf **Spanish:** Filemón de Timor
Other common names: Plain Friarbird

Taxonomy. *Tropidorhynchus inornatus* G. R. Gray, 1846, no locality = Kupang, Timor. Forms a superspecies with *P. brassi*, *P. citreogularis* and *P. kisserensis*. Proposed race *robustus* (described from Mt Ramelan, in E Timor) is considered inadequately differentiated to warrant recognition. Monotypic.

Distribution. Timor, in E Lesser Sunda.

Descriptive notes. 24 cm. Small friarbird with moderately long and slightly decurved bill without protuberance at base. Plumage is plain brownish-grey above, with pale grey and rather downy hindneck and side of neck forming obvious half-collar; darker brown face formed by dark ear-coverts and small patch of dark bare skin on lores and beneath and just behind eye; thin olive edges on remiges (faintly paler panel on folded wing), fine olive edges on rectrices; silvery white chin and throat merging to dusky grey and white-mottled lower throat; breast and belly very pale greyish-brown, diffuse streaking or scaling on breast (formed by slightly elongated and pointed feathers with off-white tips) merging to off-white or very pale grey lower

underbody; iris dark brown; bill black; legs dark grey to black. Sexes alike in plumage, male probably on average slightly larger than female. Juvenile is browner above than adult, with more distinct but diffuse yellow-green panel on wing, yellow wash on chin, throat and breast. **VOICE.** Song a medley of moderately loud notes, including a rapid series of similarly pitched "t-chika wook..." lasting 6-5 seconds with c. 2 notes per second; also gives irregular series of seesawing notes, often before song.

Habitat. Primary and secondary monsoon forest, open woodland, open scrub, occasionally lightly wooded cultivation; sea-level to 2400 m.

Food and Feeding. No details on diet. Forages mainly in canopy; seen singly or in twos (possibly pairs); noisy, aggressive and conspicuous.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Restricted-range species; present in Timor and Wetar EBA. Very poorly known. Considered widespread and common within small global range. No estimates of population.

Bibliography. Coates & Bishop (1997), Mayr (1944a), Noske & Saleh (1996), Stattersfield *et al.* (1998), Trainor, Coates *et al.* (2007), Trainor, Santana *et al.* (2008), White & Bruce (1986).

165. Brass's Friarbird

Philemon brassi

French: Polochion de Brass **German:** Mamberamolederkopf **Spanish:** Filemón de Brass
Other common names: Brass's (s) Friarbird

Taxonomy. *Philemon brassi* Rand, 1940, Bernhard Camp, Idenburg River, north-west New Guinea. Forms a superspecies with *P. inornatus*, *P. citreogularis* and *P. kisserensis*. Monotypic.

Distribution. Upper Mamberamo Basin (Idenburg R, lower Mamberamo R, probably also Rouffaer R) and Wapoga Basin (Tirawiwa R and Logari R), in W New Guinea.

Descriptive notes. 21-22 cm. Small, rather slender friarbird, with long, heavy and slightly decurved bill with no protuberance at base. Plumage is largely plain dark olive-brown above, slightly darker, blackish-brown, on remiges and rectrices, with extensive area of largely bare slate-grey to blackish-grey skin on forehead, supercilium, lores and around eye, flecked with small, sparse, varying grey and white feathering on lores and around eye; crown, nape, ear-coverts and malar region dark grey, flecked with white; chin and upper throat conspicuously white, and feathers of upper breast dark grey, finely spotted or flecked with

white; underbody pale grey, slightly darker on breast and tinged brown on thighs; underwing dull off-white with dark trailing edge and tip; plumage becomes much paler, greyish-brown, with wear; iris dark brown; bill black; legs dark grey to blue-grey. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but with rufous tinge on top of head and mantle, back and scapulars, conspicuous olive outer edges on remiges, olive edges on rectrices (lost with wear), and more brownish breast; immature like adult but retains juvenile remiges and rectrices, and probably some or all upperwing-coverts, also has white tips on otherwise dark scapulars, back and rump, less obvious spotting on throat, and sometimes yellowish tinge on lower throat or upper breast (possibly varying between sexes). **VOICE.** Noisy; only vocalization described is an upslurred call note typical of genus.

Habitat. On Idenburg R, common in flooded canegrass and dense riparian secondary growth around a lagoon; on Tirawiwa and Logari rivers, locally common in vegetation along river edge and in disturbed areas, and over (but not in) canegrass. Recorded at c. 50 m and at 80-275 m.

Food and Feeding. Nectar, fruit and insects; one fed low down in flowering *Elaeocarpus* overhanging river. Not so noisy or pugnacious as *P. buceroides*. On Idenburg R, commonly in small parties of about twelve individuals; seen to congregate with other nectarivorous birds in flowering trees.

Breeding. Male with enlarged gonads in Mar. No other information.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in North Papuan Lowlands EBA. One of least known of New Guinean birds. No estimates of population. Found to be common at two sites in recent surveys (1998) in Wapoga Basin, though not recorded in recent surveys (2000) on Mamberamo R. Appears secure at present, with much lowland forest of Mamberamo R and Idenburg R within Foja Nature

Reserve, and the region is largely inaccessible and undisturbed. Potentially threatened, however, by timber-harvesting and agricultural schemes, and a proposed dam on the Mamberamo Gorge.

Bibliography. Anon. (2007a), Beehler (1985), Beehler *et al.* (1986), Butchart & Stattersfield (2004), Collar *et al.* (2001), Mack & Alonso (2000), Rand (1940a, 1942b), Rand & Gilliard (1967), Richards & Suryadi (2002), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

166. Little Friarbird

Philemon citreogularis

French: Polochion à menton jaune **German:** Glattstirn-Lederkopf **Spanish:** Filemón Goligualdo
Other common names: Yellow-throated Friarbird, (Little) Leatherhead

Taxonomy. *Tropidorhynchus citreogularis* Gould, 1837, interior of New South Wales, Australia. Forms a superspecies with *P. inornatus*, *P. brassi* and *P. kisserensis*; often treated as conspecific with last of those. Nominant race intergrades with *sordidus* in Queensland (from near Cape York S to around Georgetown); also exhibits slight clinal variation in size, with decrease in length of wing and increase in length of bill from S to N. Additional proposed races in Australia are *occidentalis* (described from Derby, in N Western Australia), *breda* (from Melville I), *johnstoni* (from Johnston R, in N Queensland) and *carpentariae* (from Normanton, in NW Queensland), but all of these represent only minor and clinal variation in size and tone of plumage. Three subspecies recognized.

Subspecies and Distribution.

P. c. papuensis Mayr & Rand, 1935 – CS New Guinea (Merauke E to Oriomo R).

P. c. sordidus (Gould, 1848) – N Western Australia (mainly N of 19° S, including many offshore islands) E through Top End of Northern Territory (including Melville I, Groote Eylandt and Sir Edward Pellew Is) to NW Queensland (S to Selwyn Range).

P. c. citreogularis (Gould, 1837) – Queensland (from Cape York Peninsula and E of Diamantina Drainage Basin) to New South Wales (largely absent E of Great Divide in SE), N Victoria and extreme CE South Australia (along Murray R).

Descriptive notes. 27 cm (25-29); male 58-71 g and female 59-84 g (nominant), male 50-77 g and female 48-76.5 g (*sordidus*), one male 53 g and one female 55 g (*papuensis*). Large honeyeater with moderately long and slightly decurved bill (lacking casque), and long tail with tip appearing slightly notched when folded and square-cut when spread. Nominant race is brown-grey above, with downy paler grey half-collar (hindneck to side of neck); diagnostic blue-grey triangular bare patch across malar area and ear-coverts and as a separate narrow strip above eye, bordered above by dark brown and finely pale-scaled lores, thin

line of feathering above eye and triangular patch behind eye, and bordered behind by black at rear of ear-coverts; thin white edges of remiges (faintly paler panel in folded wing) and narrow off-white tip of tail; silvery white chin and throat, duller greyish lower throat; breast light brown-grey, sparsely and finely streaked white, merging to paler grey or grey-white on flanks and much of belly, and to whitish in centre of lower belly, vent and undertail-coverts; undertail light grey, narrow off-white tip and edges of rectrices; underwing light grey-brown, narrow white scaling on outer wing-coverts and darker grey-brown trailing edge and tip; iris brown to dark brown, black orbital ring; bill black, or black with blue-grey base and gape; legs slate-grey to black. Sexes alike in plumage, male slightly larger than female. Juvenile is similar to adult but slightly browner above (including marginal and median secondary coverts), with fine paler brown scaling throughout, fine yellow-green edges on greater coverts and remiges (greenish panel on folded wing), narrow whitish fringes at tips of primaries, fine yellow-green edges and slightly wider pale tip on rectrices (suffused brownish in centre), bright yellow chin and throat merging to warm-brown breast tinged yellow, gape yellowish and swollen, and some have downy band across lower throat continuous with hindneck-collar; immature similar to adult but appearance varies greatly with wear and fading during first year, initially differs from adult in bold white scalloping on upperbody, bright yellow chin and upper throat merging to yellow wash on lower throat and upper breast, which also overlaid with scattered fine yellow streaks and (on lower breast), fine white streaks, prominent yellow patch on side of lower breast, also retains juvenile tail and remiges and some or all upperwing-coverts; with wear and fading in first year plumage much more adult-like, with upperbody plain brown-grey (white scalloping reduced or lost), chin and throat whitish, usually with few yellow-tipped feathers on throat, and yellow of lower throat and breast much reduced. Races differ only slightly in plumage (mainly colour and pattern of underbody) and size (especially bill): *sordidus* is similar in size to nominate but with significantly longer bill, has slightly browner and mottled upperparts, slightly darker, dirty grey underbody, diffuse dusky mottling on breast; *papuensis* is smaller than nominate, and generally darker, with bolder white feather tips on breast, bare facial skin possibly paler, light blue-grey, and iris described as grey (not brown) but confirmation needed. **VOICE.** Not well known. Variety of calls, and can be very noisy (though usually not so noisy as larger congeners). Song in breeding season in Australia consists of a mellow somewhat melodic "che-weep, che-wip, che-wip, che-will, che-will", elements of songs can be given separately, e.g. in New Guinea often a repeated, moderately high-pitched, liquid mellow double whistle, "tlew" or "chiew", probably elements of song. Also utter continuous discordant chatter, especially when in flocks, and short note in alarm; repeated call given occasionally while advancing towards feeding conspecific.

Habitat. In New Guinea occupies savanna woodland and monsoon forest. In Australia common in wide range of open sclerophyll forests and woodlands dominated by eucalypts, typically with grassy ground layer or sparse understorey of shrubs and grasses, though sometimes with denser understorey of shrubs or a secondary layer of trees and saplings, e.g. forest and woodland dominated by river red gums (*Eucalyptus camaldulensis*) and often with understorey of *Acacia* or, in riparian associations, dense stands of lignum (*Muehlenbeckia*), or woodland dominated by black box (*Eucalyptus largiflorens*) and coolibah (*E. coolabah*) with understorey of saltbush (*Atriplex*); also often in mixed forest or woodland combinations of *Eucalyptus*, *Acacia*, e.g. brigalow (*Acacia harpophylla*), gidgee (*Acacia cambagei*) or mulga (*Acacia aneura*), cypress-pine (*Callitris*) or casuarina, with understorey of scattered trees and shrubs, or in mixed woodland dominated by broadleaf species such as *Excoecaria* and *Bauhinia*, with *Eucalyptus*, *Terminalia* and *Atalaya* present, and sparse layer of shrubs over grassy ground layer. Recorded also in range of other woodland or forest associations, including riverine or swamp paperbark (*Melaleuca*) forest, woodlands or thickets (particularly in N Australia), and *Acacia* woodlands or thickets, e.g. of gidgee, mulga, brigalow, pindan (*Acacia tumida*) or lancewood (*Acacia shirleyi*); less often, riverine forest dominated by casuarina or silky oak (*Grevillea robusta*), or woodland or low forest of *Banksia*. Common in some modified

habitats, particularly with flowering trees, such as parks and gardens in towns and cities, orchards, or isolated trees or remnants in agricultural land. Sometimes in coastal heathland, shrubland or scrub, or in mangroves; very rarely in wet sclerophyll forest, mallee, or patches of monsoon rainforest. From coast and inland slopes and plains to at least 900 m in Australia; lowlands in New Guinea.

Food and Feeding. Predominantly nectar and invertebrates (mainly insects, also spiders); also flowers, fruit and seeds. Forages at all levels, mostly in trees and shrubs and often in canopy. Exploits wide variety of substrates: frequently at flowers, but also inner and outer foliage and, sometimes, dead foliage, bark of trunks and large branches of trees (including dead branches), stems, and in shrubs; only occasionally on ground or in air. Nectar obtained by probing flowers; gathers invertebrates mainly by gleaning (including from nectar-bearing flowers), also by flutter-chasing (scrambling roughly through foliage and catching dislodged arthropods as they fall or land below), sallying (including sally-striking at foliage or in air and sally-hovering), and by probing. Near Darwin, in Northern Territory, foraged on flowers that provide best sources of nectar, mainly those with stameneriferous cups, e.g. *Eucalyptus* (50-3%), brush inflorescences, e.g. *Banksia* and *Melaleuca* (9-8%) and gullet-shaped flowers, e.g. *Grevillea* (12-3%). Usually singly, in twos (probably pairs), or in small loose parties of 6-20 individuals at food sources, such as flying insects around tops of trees or at flowering eucalypts, paperbarks or grevilleas; large gatherings, of up to 500, occasionally reported. Often forages with other honeyeaters, especially *P. corniculatus* and *Anthochaera carunculata* in Australia, and *P. buceroides* and *P. corniculatus* in New Guinea; in NE Queensland, seen feeding in mixed-species flocks with up to five other meliphagid species.

Breeding. Nestlings recorded in Apr and late Oct and fledglings early Apr in New Guinea; in Australia season Aug-Apr (clutches Sept-Apr in N, Aug-Feb in E & SE); possibly double-brooded. All following details from Australia. Nest a large, deep, open and loosely woven cup, sometimes frail (contents visible from below), usually made of strips of bark, grass or plant stems and vines, bound with spider web or wool, lined with finer grass, plant fibre, rootlets and feathers (other materials include rootlets, twigs and leaves, casuarina needles, hair), external diameter 11-4-14 cm, depth 8-4-10-2 cm, internal diameter 7-6-10-2 cm, depth 5-7-8-9 cm; supported by rim in fork or twigs, often in outer branches or drooping foliage, sometimes in mistletoe (Loranthaceae), nearly always in live tree near or overhanging water and often well concealed among dense foliage, 1-19 m (mean 6-3 m) above ground; often in same tree as, or near, active nest of Magpie-lark (*Grallina cyanoleuca*) or Willie Wagtail (*Rhipidura leucophrys*) or, less often, a range of other species. Clutch usually 2-3 eggs, sometimes 4, mean 2-44 (mean clutch size possibly decreasing from S to N); incubation probably by female only, period 13-16 days; chicks fed by both sexes, nestling period 13-15 days; one brood fed for 10 or more days after fledging. Nests parasitized by Common Koel (*Eudynamis scolopacea*). From 24 eggs in nine nests at which outcome known, overall success 0-67 fledged young per nest.

Movements. Not properly known. Appears largely resident throughout range, but partly migratory in SE Australia; undertakes at least local, or possibly regional, movements to exploit spatial and temporal variation in nectar and insect resources; occurrence or abundance often associated with flowering of foodplants. Widely classed as nomadic, but many such observations probably refer to local or regional movements. General tendency to shift towards N tropics for winter and to vacate N extremes of range in wet season; over much of N Australia appears predominantly resident, or occurs throughout year, but some indication of partial seasonal movement towards coast in dry season, and appears to vacate S Northern Territory range in winter; also highly mobile at local scales, and numbers at sites correlated with flowering, e.g. at Berry Springs (Northern Territory) density strongly and positively correlated with overall availability of nectar. At least partly migratory in S & SE of range; migratory populations move N in autumn and early winter, and return S from mid-winter to early to late spring (return to SW New South Wales as late as Oct in some years); extent of N migration not known, but some passage to SE Queensland, and some indication of augmentation of NE populations with migrants. Some occurrences relate to climatic factors, e.g. irregular occurrence or concentrations in SE & NE Australia attributed to drought or sustained winds. Scattered records outside normal range; vagrants on islands of Torres Strait possibly of nominate race.

Status and Conservation. Not globally threatened. In New Guinea generally fairly common to common, and locally abundant; common in Australia. No estimates of total abundance, but recorded densities of 0-03-6-13 birds/ha in Australia.

167. Grey Friarbird

Philemon kisserensis

French: Polochion de Kisar **German:** Graulederkopf **Spanish:** Filemón de la Kisar

Taxonomy. *Philemon kisserensis* A. B. Meyer, 1884, Kisar, south Banda Sea, Lesser Sundas. Forms a superspecies with *P. inornatus*, *P. brassi* and *P. citreogularis*; often treated as a race of last, but such treatment anomalous in relation to biogeography of these species. Monotypic.

Distribution. Kisar, Leti and Moa, off E Timor, in E Lesser Sundas.

Descriptive notes. 25 cm. Rather small friarbird, with moderately long and slightly decurved bill lacking casque. Plumage is plain brownish-grey above, with narrow off-white tip of uppertail, and thin pale edges of remiges; fairly narrow and triangular blue-grey bare facial patch bordered above by narrow dark brown and finely scaled paler lores and supercilium, and bordered behind by black-brown rear ear-coverts; pale grey to silvery grey downy half-collar on hindneck and side of neck; chin and upper throat white to silvery white, merging to pale brownish-grey lower throat and breast overlaid with some whitish streaks;

brownish-grey of breast merges with paler grey or greyish-white lower underbody, palest in centre of lower belly, vent and undertail-coverts; undertail light grey with narrow off-white tip and edges, underwing light grey-brown with darker grey-brown trailing edge and tip; iris brown to dark brown; bill black or grey-black; legs slate-grey to black. Sexes alike in plumage, male probably larger than female. Juvenile and immature undescribed. VOICE. No information.

Habitat. No information.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not assessed. Status uncertain, as generally listed as race of *P. citreogularis*; probably not globally threatened. Restricted-range species; present in Banda Islands EBA. Very poorly known, and no current information on biology or status. Formerly considered common, and possibly still is.

Bibliography. Coates & Bishop (1997), Trainor (2003b), White & Bruce (1986).

168. Meyer's Friarbird

Philemon meyeri

French: Polochion de Meyer **German:** Zwerglederkopf **Spanish:** Filemón de Meyer
Other common names: Dwarf Friarbird

Taxonomy. *Philemon meyeri* Salvadori, 1878, Rubi, Geelvink Bay, north-west New Guinea. Monotypic.

Distribution. Widespread in New Guinea from Bomberai Peninsula (Fakfak Mts and Kumawa Mts), and E from head of Geelvink Bay and, in S, E from Fly R.

Descriptive notes. 22 cm; male 53-58 g, female 46-54 g. Small, rather drab and non-descript friarbird with proportionately long, moderately heavy and slightly decurved bill lacking protuberance at base, and with little bare skin on head. Plumage is uniformly dark grey-brown to dusky brown above, faintly and diffusely streaked blackish-brown, and paler grey-brown below, with small area of bluish-black to blackish bare skin over lores and narrowly around eye; plumage becomes much browner with wear and fading; iris dark brown; bill black; legs slate-grey. Sexes alike. Juvenile is similar to adult, but back to uppertail-coverts finely scaled or spotted off-white, outer secondaries and inner primaries finely edged yellow-olive (diffuse pale panel on folded wing), rectrices also finely edged yellow-green, throat washed bright bronze-yellow, upper breast diffusely barred dark brown and bronze-yellow (by time when wings and tail fully grown, warm brown of lower throat and breast are broken up by beginnings of immature plumage, with prominent yellow patch on side of breast and bright yellow wash on lower throat and upper breast); immature like adult, but with bronze-yellow wash across upper breast. VOICE. At times calls loudly for long periods from exposed perch high in tree. Advertising call is a short but loud, high-pitched and downslurred whistled "tiew", "teeuw" or "weeeeu", repeated several to many times at intervals of 2-3 seconds or longer, and often given in middle of day. Song a jumbled series of 12 or more notes alternating in pitch (a tone apart), "peet o weet" or "wee to wee to wee to...", delivered at rate of 5 notes per second, similar to call of *Xanthotis flaviventer*.

Habitat. Rainforest, forest edge, swamp-forest, tall and dense secondary growth and other disturbed areas, such as sides of roads and tracks. In examination of vegetation succession (from gardens to forest) resulting from slash-and-burn agriculture in lowland New Guinea, recorded mainly in late regrowth and undisturbed habitat. Lowlands to c. 1200 m; to 300 m in Kumawa Mts and to 700 m in Fakfak Mts.

Food and Feeding. Fruit, nectar and insects. Mainly in upper canopy, at times descending to upper levels of middle stage or lower in dense secondary growth. Forages mainly in dense outer or upper foliage of crowns of trees (where can be difficult to see), but sometimes in leafless trees; often in flowering trees, including patches of low sago palms (*Metroxylon*). Of 71 observations of foraging in lowland rainforest at Brown R, most in upper canopy 30-35 m above ground (54%) and lower canopy 25-30 m above ground (39%), with rest in subcanopy at 8-25 m (7%); not recorded as foraging in understorey or emergent trees. Usually seen singly or in twos (probably pairs); sometimes with other species in flowering trees; chases smaller honeyeaters from trees.

Breeding. One clutch of 2 eggs (described). No other information.

Movements. Few data. Resident at Brown R, in S New Guinea; may move locally from hill forest to lower altitudes to exploit flowering trees.

Status and Conservation. Not globally threatened. Not well known. Considered generally common to abundant; e.g. abundant in Lakeamu Basin. Density in lowland rainforest near Brown R 0-2 birds/ha.

Bibliography. Anon. (1978a), Bailey (1992), Beehler (1995), Beehler *et al.* (1986), Bell (1969, 1970c, 1982a, 1982c), Bowman *et al.* (1990), Coates (1990), Coates & Peckover (2001), Diamond (1972a, 1985), Finch (1980b, 1983), Fletcher (2000b), Gilliard & LeCroy (1967a, 1968), Hartert (1930), Mack (1998), Mack & Alonso (2000), Mayr & Rand (1937), Pearson, D.L. (1975), Rand (1942a), Rand & Gilliard (1967), Richards & Suryadi (2002), Schönwetter & Meise (1981).

Genus *MELITOGRAIS* Sundevall, 1872

169. White-streaked Friarbird

Melitograis gilolensis

French: Polochion strié **German:** Halmaheralederkopf **Spanish:** Filemón Estriado
Other common names: White-streaked Honeyeater, Bonaparte's/Gilolo/Striated Friarbird

Taxonomy. *Tropidorhynchus gilolensis* Bonaparte, 1850, Gilolo Island = Halmahera. Genus formerly subsumed in *Philemon* and considered closely related to latter. Monotypic.
Distribution. Morotai, Halmahera, Kasiruta and Bacan, in N Moluccas.

Descriptive notes. 23 cm; one male 54 g. Distinctive medium-large friarbird-like honeyeater with long, heavy, decurved bill that appears to droop distally. Has top of head off-white, finely streaked dusky grey-brown, patch of bare blue skin from lores and broadly around eye continuing in band from rear of eye across nape; rest of head, neck and upperparts largely brownish-black with olive tinge, with fine white shaft streaks on upperbody; upperwing dark chestnut-brown, richer than rest of upperparts, and uppertail brown; underparts dark brown, with fine white shaft streaks on chin, throat and breast; iris dark, blackish; bill

blackish; legs dark grey to blackish. Sexes apparently alike. Juvenile and immature undescribed. Voice. Main call a moderately high to high-pitched unmusical note, given at rate of c. 1 per second. Also utters harsh rasping note.

Habitat. Inhabits lowland and montane forests, including swamp-forest, forest edge and remnants in grassland and cultivated areas, selectively logged forest and regrowth forest, as well as coconut

plantations and mangroves. Recorded from sea-level up to 960 m on Halmahera, and up to 2130 m on Bacan.

Food and Feeding. Apparently mainly arthropods and nectar, but also small fruits. Forages in flowering trees and shrubs; gleans for arthropods. Quiet and inconspicuous; usually seen singly, also in twos (probably pairs) or in small parties. Aggressive, but sometimes forages with other species, e.g. seen in canopy of flowering *Albizia* with flowerpeckers (*Dicaeum*), sunbirds (of genera *Leptocoma* and *Cinnyris*) and leaf-warblers (*Phylloscopus*), though with much chasing; on Halmahera and Bacan single birds apparently defended crowns of flowering trees, and one seen to chase and disperse a small flock of Northern Golden Bulbuls (*Thapsinillas longirostris*), and another defended a flowering *Erythrina* tree, continually darting out at other birds that attempted to feed in tree. On Halmahera, often forages with *Myzomela obscura*, which people of Jailolo region consider to be the young of present species.

Breeding. Male with enlarged gonads in Sept. No other information.

Movements. No information; probably resident, with some local movements.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Moderately common on Halmahera; earlier was considered scattered and seen only infrequently on Halmahera and Bacan.

Bibliography. van Bemmelen (1948), Coates & Bishop (1997), Poulsen & Lambert (2000), Ripley (1959d, 1961b), Statfield *et al.* (1998), White & Bruce (1986).

X. p. septentrionalis Mayr, 1931 – mountains of N New Guinea from Mamberamo R E, including Cyclops Mts and mountains of Sepik R region, to Adelbert Mts.
X. p. lophotis Mayr, 1931 – mountains of Huon Peninsula and SE New Guinea (E from at least Karimui).
X. p. candidior Mayr & Rand, 1935 – S New Guinea (S Trans-Fly region).

upper ear-coverts; ear-coverts bordered behind by bold yellow auricular plume that angles up and back onto side of neck; mantle, back and scapulars dark olive-brown, boldly but irregularly barred or scaled white and overlaid with varying olive-green wash (sometimes white spotting of hindneck

Descriptive notes. 15–17 cm; male 19.7–23.5 g and female 18–19.5 g (*lophotis*), 19 g and 25 g (*poikilosternos*), one male 20 g (*kuehni*). Distinctive, medium-small honeyeater with moderately long and slightly decurved bill. Race *lophotis* has top and side of head and neck dark olive-brown to black-brown, fine white spotting on hindneck; large, fleshy partial orbital ring yellow to yellow-orange above eye, merging to pink behind or below eye (or both), or to grey beneath eye, broken at front by blackish lores and bordered below by blackish moustachial stripe that continues across lower ear-coverts, isolating small patch of pale grey on

continues onto upper mantle), rump and uppertail-coverts olive-brown to brownish-olive; uppertail olive-brown, slightly greener edges of rectrices; upperwing dark brown to dark olive-brown, small off-white to olive-white tips on smaller wing-coverts, yellowish-olive fringes and larger off-white tips (sometimes tinged olive) on greater coverts, fairly broad yellowish-olive outer edges on remiges (strong olive panel on folded wing); chin and throat pale grey, short, narrow and diffuse blackish malar stripe; underbody cream to pale creamy buff, weak olive tinge at side of breast, and fine olive-brown streaking over upper breast merging into boldly flecked or spotted lower underbody, large bold triangular marks throughout, most densely on lower breast (where black markings enclose small white spot at tips); undertail brownish-grey, olive tinge at edges of rectrices; underwing-coverts white, merging to buff across bases of remiges, and with silvery grey-brown trailing edge and tip; iris black-brown to black; bill black; legs grey. Sexes alike in plumage, male larger than female. Juvenile is like adult, but auricular plume paler, sometimes washed grey, mantle, back and scapulars tinged yellowish-olive, rufous-buff tips on upperwing-coverts, fine buff tip on tail, underparts less boldly spotted, gape yellow and more prominent than in adult. Race *candidior* is like *lophotis*, but black of feather centres of back less distinct, and underbody whiter, with finer black streaking and smaller black spotting or flecking; nominate race lacks yellow auricular plume; *kuehni* has top of head olive with dusky mottling or streaking, prominent yellow auricular plume, and yellow tinge on mantle, back and scapulars; *poikilosternos* has much-reduced auricular plume, olive tinge on top of head, and yellowish tinge on mantle, back and scapulars and underbody; *septentrionalis* has auricular plume barely visible, upperparts slightly paler and duller than previous and with only very fine white streaks or speckles, greyish underbody lacking olive tinge, also iris of one adult male described as blue-grey. **Voice.** Fairly quiet, but small groups can be noisy. Vocalizations include brief upslurred disyllabic musical whistle, “wu-dée”, repeated many times at intervals of 1.5–3.5 seconds; repeated trisyllabic phrase from individuals in small parties; occasional “tup”. Main vocalization also described as a repeated mechanical series of notes in descending pattern.

Habitat. Lowland, foothill and lower montane primary rainforest, foothill monsoon forest, secondary forest, edges of forest and, in lowlands, dense savanna. Sea-level to c. 1500 m; mainly in foothills and lower mountains, but commonly in lowlands in Trans-Fly region and around Port Moresby, and locally at base of foothills.

Food and Feeding. Primarily insectivorous; also takes nectar and fruit, including figs (*Ficus*). Forages mainly in canopy to lower middle storey (including on vines), as well as in understorey. Of 97 observations of foraging in lowland rainforest at Brown R (in SE of range), most were in understorey (49%), including 35% from ground to 2 m above ground) and in upper canopy at 30–35 m (37%), with fewer in lower canopy 25–30 m above ground (7%) and in subcanopy at 8–25 m (7%); not recorded foraging in emergent trees; in Eastern Highlands, when in flowering trees, foraged evenly in upper canopy and in lower canopy. Distribution of foraging heights reflects types of food being sought, with most nectar-feeding in canopy and much insectivory at lower levels. Typically forages in foliage, especially among dead curled leaves, gleaning arthropods (including caterpillars), but also in flowering or fruiting plants. At Brown R study site foraged mostly

among flowers (70% of observations) and foliage (18%), with rest on branches (7%) of rainforest trees and at fruits (5%); all observations described as involving gleaning, but this probably includes probing. Usually seen singly, less often in twos or threes; sometimes associates loosely with other meliphagids or other bird species at food sources, and commonly displaced by similarly sized congener *X. flaviventer* in flowering trees in Eastern Highlands; sometimes in mixed-species flocks.

Breeding. Single record (without details) in Mar, and indirect evidence of breeding in Sept (one in breeding condition), Oct (three females with ovaries enlarged or becoming enlarged) and Jan (three in breeding condition). No other information.

Movements. Few data. Resident at Crater Mt and Brown R (E & SE New Guinea), probably with some local movements. Only recoveries of ringed birds were at site where initially ringed, and more than one year later.

Status and Conservation. Not globally threatened. Generally common to uncommon. Estimated density in lowland rainforest near Port Moresby (SE New Guinea) 1 bird/10 ha. No estimates of global population.

171. Macleay's Honeyeater

Xanthotis macleayanus

French: Méliphage de Macleay **German:** Kappenhonigfresser **Spanish:** Mielero de Macleay
Other common names: Buff-striped/Mottled/Mottle-plumaged/Yellow-streaked Honeyeater

Taxonomy. *Ptilotis macleayana* E. P. Ramsay, 1875, Cardwell, Rockingham Bay, Queensland, Australia.

Genus formerly subsumed in *Meliphaga* by some authors. Monotypic.

Distribution. NE Queensland from Cooktown S, including Hinchinbrook I and extending inland to W slopes of Atherton Tableland, to S Paluma Range, and occasionally farther (to The Pinnacles, SW of Townsville), in NE Australia.

Descriptive notes. 17–21.5 cm; male 30–39 g, female 25.5–31 g. Highly distinctive, medium-sized honeyeater with rather short tail, and long, rather hefty, slightly decurved bill. Has top of head and neck dull black, spotted white on centre of nape and hindneck; orange-brown lores, eyering and malar area combine to form pale patch surrounding eye and enclosing prominent narrow white gape-stripe and pinkish-white subocular patch, bordered behind and below by golden-yellow to ochre plumage across upper ear-coverts; chin, throat and side of neck pale grey, with olive wash on lower throat; upperbody blackish-brown, diffuse yellowish streaking on

mantle merging to bold white streaking on scapulars, and with diffuse olive mottling on rest of upperbody; uppertail and upperwing dark brown, all rectrices with narrow greenish-yellow edges, bold white streaks at tips of smaller secondary coverts, narrow greenish-yellow edges and white “rosethorns” at tips of greater coverts and tertials, narrow greenish-yellow edges on remiges; upper breast pale grey with olive-yellow wash and yellowish-white streaking, diffuse greenish-yellow patch at side of upper breast; lower breast, belly and upper flanks coarsely streaked blackish-brown and white, merging to almost uniform greyish-brown on lower underbody; undertail dark grey; underwing pale yellow along leading edge, merging to pink-buff on greater coverts and bases of remiges, and with dark grey trailing edge and tip; iris black-brown, narrow light grey orbital ring; bill black; legs blue-grey. Sexes alike in plumage, male larger than female. Juvenile is very similar to adult but duller overall, with smaller and duller pale spotting and streaking on nape, hindneck and upperbody, paler and greyer below, with fainter pale streaking and very faint olive-yellow wash on breast. **VOICE.** Calls loud and conspicuous, but species usually quiet. Song a rapid somewhat musical call of 2 or 3 disyllabic notes, rendered “t-wit, t-weee, t-whit” or “chewit-che-wew” or as brisk rollicking “pchee, cherreep”. Also utters single loud ringing “chip” and a churring call.

Habitat. Mainly rainforest, mostly low-altitude forests (including mesophyll vine forest and complex notophyll vine forest), but also often at rainforest edges, in open *Eucalyptus* forests and woodlands, and in parks, gardens and orchards in towns, also in picnic grounds within rainforest; occasionally in mangroves. May prefer primary rainforest over secondary forest, but often recorded in secondary growth and, sometimes, logged forest. Sea-level to c. 1100 m.

Food and Feeding. Mainly insectivorous; also takes nectar and fruit, including small figs (*Ficus*). Forages at all levels of forest, particularly upper and middle storeys, but mainly in canopy; mostly among foliage of crowns of trees and epiphytes or vines, or on bark. In rainforest at Lacey's Creek, foraged mainly in canopy and sometimes in emergent trees, only rarely on ground; searched mainly in clumps of dead foliage and among live foliage, twigs and small branches, with rest of foraging time spent at flowers, fruits and seeds, or in air. Also seen to feed at sap-flows from incisions cut into trunks of *Eucalyptus* trees by yellow-bellied gliders (*Petaurus australis*). Captures insects by gleaning and probing, and probes flowers for nectar, often hanging upside-down while feeding; also sallies for insects, and reported as sometimes climbing trunks in manner of Australasian treecreeper (*Climacteridae*). Active, but quiet and unobtrusive; can be noisy when foraging through dead foliage. Usually seen singly or in twos (probably pairs), sometimes in small flocks, and may gather in groups of up to 30 individuals at food sources (including birdfeeders); sometimes forages with other species, such as Victoria's Riflebird (*Ptiloris victoriae*), *Meliphaga lewinii*, *Myzomela obscura* and Silvereye (*Zosterops lateralis*). Aggressive towards conspecifics and other species of similar size.

Breeding. Poorly known. Breeding (including fledglings) reported in Sept–Dec and Feb–Mar, with eggs Oct–Dec and nestlings Oct. Nest a rather small, deep cup made of palm fibre, small leaves, bark or other plant material, and some spider egg sacs, lined with palm fibre and a few feathers, one nest had external diameter 8.3 cm, depth 10.2 cm, internal diameter 5.7 cm, depth 6.4 cm; attached by rim to several twigs or in thin forked horizontal branch, in vines or other foliage, usually in crown of tree but sometimes in shrub. Clutch 2 eggs; female incubates, but not known if male assists, and both parents feed nestlings; no information on duration of incubation and nestling periods

Movements. Resident; possibly some seasonal altitudinal movements near Cooktown, moving to higher altitudes in Dec–Jan.

Status and Conservation. Not globally threatened. Restricted-range species: present in Queensland Wet Tropics EBA. Locally common. No estimates of numbers or density.

172. Tawny-breasted Honeyeater

Xanthotis flaviventer

French: Méliphage à ventre fauve

Spanish: Mielero Ventrihabano

German: Ockerbrust-Honigfresser

Other common names: Tawny-breasted/Brown Xanthotis, Buff-breasted/Streaked/Streak-naped/Honey-breasted/Rufous-breasted/Brown(!) Honeyeater

Taxonomy. *Myzantha flaviventer* Lesson, 1828, Dorey = Manokwari, Vogelkop Peninsula, New Guinea. Genus formerly subsumed in *Meliphaga* by some authors. Species sometimes referred to by name of *X. chrysotis*; was originally described under name *Philedon chrysotis*, but this invalid, as preoccupied, and species subsequently renamed. Taxonomy not fully understood, and number of races recognized varies from fewer than ten to 14; validity of those listed below requires confirmation. Races intergrade where they meet, and several proposed races appear to be from zones of intergradation: *rubensis* (described from Rubi, at head of Geelvink Bay) is probably an intergrade between nominate and *saturator*; *giulianietii* (Avera, on Aroa R, in SE New Guinea) is between *saturator* and *visi*; and *kumusi* (Kumusi R, on N coast of SE New Guinea) is considered an intergrade between *visi* and *madaraszii*. Further, described race *tararae* (Tarara, Wassi Kussa R, c. 140 km W of Daru, in S Trans-Fly) is synonymized with *saturator*, and *austera* (Tamulol, on Misool I) with nominate. On basis of plumage characters, races fall into five groups: greenish nominate and *fusciventris*; plain dusky grey *meyeri*, *philemon* and *madaraszii*; rufescent *visi*; white-faced and ventrally spotted *spilogaster*; and bare-faced and fawn-breasted *filiger* and *saturator*. Nine subspecies tentatively recognized.

Subspecies and Distribution.

X. f. fusciventris Salvadori, 1876 – Waigeo and Batanta, in West Papuan Is.

X. f. flaviventer (Lesson, 1828) – Salawati and Misool (West Papuan Is), and NW New Guinea Vogelkop.

X. f. meyeri Salvadori, 1876 – Yapen I, in Geelvink Bay (NW New Guinea).

X. f. philemon Stresemann, 1921 – N New Guinea from Mamberamo R E to Huon Peninsula.

X. f. madaraszii (Rothschild & E. J. O. Hartert, 1903) – NE New Guinea (E from Astrolabe Bay to Huon Peninsula and Markham Valley, S to Wau).

X. f. saturator (Rothschild & E. J. O. Hartert, 1903) – Aru Is, S New Guinea (from Mimika R E to Fly R and Gulf of Papua), and islands in N Torres Strait (including Saibai, Boigu and Daru).

X. f. visi (E. J. O. Hartert, 1896) – S & SE New Guinea E from Huon Gulf and Gulf of Papua to about Milne Bay.

X. f. spilogaster (Ogilvie-Grant, 1896) – Trobriand Is and D'Entrecasteaux Archipelago (including Goodenough, Ferguson and Normanby), off SE New Guinea.

X. f. filiger (Gould, 1851) – NE Queensland (Cape York Peninsula S to about Edward R in W and to McIlwraith Range–Rocky R–Silver Plains Station in E), in NE Australia.

Descriptive notes. 18–21 cm; male 33–41 g and female 26.5–37 g (*filiger*), male 47–50 g and female 38–44.5 g (nominate), male 46–54 g and one female 40–5 g (*philemon*), sexes combined average 39 g (*visi*), male 43–54 g and female 37–49 g (*meyeri*), male 40–55 g and female 38–49 g (“*rubensis*”). Medium-sized, rather drab honeyeater with long, fairly hefty and slightly decurved bill. Nominate race is dark brown with strong olive-green tinge on top of head, neck and upperbody, with obscure fine pale-grey spotting on nape and hindneck (spots sometimes lacking); lores, malar area and narrow line of feathers around eye olive-brown,

paler than top of head, divided by bold whitish stripe of bare skin extending from gape below eye and tapering behind eye to narrow streak over upper ear-coverts; ear-coverts, side of neck, chin and throat grey (paler on chin and throat), small yellow plumbe bordering rear edge of ear-coverts; uppertail and upperwing dark olive-brown, fine olive edges on rectrices, fine buff edges on remiges (large buff panel on folded wing), fine buff flecks at tips of lesser and median secondary coverts and fine buff fringes on greater coverts (in fresh plumage, pale median-covert tips form broken wingbar); breast rufous-buff, washed with olive-yellow, grading to more rufous-brown on lower underbody; undertail dark grey, underwing rich buff with dark grey trailing edge and tip; iris black-brown to brown or red-brown, blue-grey orbital ring; bill black; legs light blue-grey to grey. Sexes alike in plumage, male slightly larger than female. Juvenile is like adult, but separable (in reasonable view) by having yellow auricular plumage smaller and less obvious, rump and uppertail-coverts diffusely washed buff, fine buff tip of tail, buff fringes and tips of secondary coverts slightly broader and bolder, longest feather of alula thinly fringed buff (all dark in adult), edges of remiges richer buff, and underbody duller. Races differ mainly in ground colour and patterning of head, neck and body, and in size: *fusciventris* is like nominate but with weaker rufous tinge on underbody, and with strong olive-green wash on breast and brownish-grey mottling on belly; *filiger* differs from nominate in being dark olive-brown (less greenish) above, grading to grey-black with fine pale grey mottling or spotting on nape and hindneck, also has rich buff (rather than rufous) breast merging to grey-buff on vent, with faint olive-green wash and faint paler streaks on upper breast, and bolder creamy streaks and spots on belly; *saturator* differs from previous in darker olive-brown upperbody, contrasting with olive-brown of top of head and grey-black and indistinctly spotted (or unspotted) nape and hindneck, little or no pale spotting on belly, and anterior part of pale facial stripe often broken and obscure (or absent); *visi* is similar to last but with much yellower facial stripe, more rufescent ground colour above, and strong yellowish-brown lower underbody; *spilogaster* also is similar, but with some obscure yellowish-white spots on breast; *philemon* is much duller, darker and plainer than preceding races, entire upperparts drab dark brown, darker blackish-brown on top and side of head,

with deep orange plume on rear edge of ear-coverts, and dull pale brown below, slightly paler and greyer on chin and throat; *meveri* is very like last, but crown on average darker, blackish, and breast greyer, with faintly darker grey mottling; *madaraszii* also is like *philemon* but paler above, with olive wash on mantle, scapulars and upper back. **VOICE.** Not noisy, but commonly heard throughout day. Main call a series of rather loud single whistles, rising and falling in pitch and loudness; in E New Guinea, consists of a phrase of usually 3 (sometimes 2) notes, "whit-wut-wu" or "whip-to-whew" (length of phrases 1–1.6 seconds), repeated 3–10 or more times (at rate of c. 6.5–7.5 phrases per 10 seconds); some variation in calls, with one to all notes in phrase disyllabic, or phrase sometimes incomplete; also some apparent geographical variation in phrases and speed of delivery. Antiphonal duets reported. In New Guinea, contact call an excited "tip-tip-tip-tip", given in flight or during foraging in mixed-species flocks, and when disturbed gives high-pitched "tjiewiet-tiet...tjiewiet-tiet" (a characteristic call of forests where it occurs). Other calls include, in New Guinea, a sharp "chup" and a weak "whuk" or "tup"; in Australia, a 3-note call, with emphasis on first or last note (possibly "which-which-which"), and chattering and scolding notes.

Habitat. Mainly dense lowland rainforest (including vine forests, gallery and other riparian associations, and monsoon scrub), forest edge, remnant forest patches, and secondary rainforest, and, in New Guinea, monsoon forest. Also, often in mangrove forests and woodlands (and largely confined to mangroves on Boigu and Saibai, in Torres Strait) and, in Australia, open eucalypt and paperbark (*Melaleuca*) forests and woodlands adjacent to rainforest; in New Guinea, also savanna and swamp-forest. In New Guinea also in many disturbed habitats, such as gardens and secondary growth along roads and tracks, occasionally in towns. On W Cape York Peninsula, isolated occurrences in semi-deciduous dune woodland. Sea-level to c. 1500 m.

Food and Feeding. Mainly insects, including beetles (Coleoptera), grasshoppers (Acridae), cockroaches (Blattodea), cicadas (Cicadidae) and caterpillars; also nectar and fruit, e.g. of figs (*Ficus*). Forages at all levels, mostly in upper canopy, less often in lower canopy and middle stages, only occasionally lower, including on ground. Of 486 feeding observations in lowland rainforest at Brown R (SE New Guinea), most foraging in canopy (total of 54% observations: 33% in lower canopy 25–30-m high, and 21% in upper canopy at 30–35 m) and subcanopy 8–25 m high (35%); rarely lower (10%) or on emergent trees (1%). In Eastern Highlands, when in canopy of flowering trees, foraged significantly more in lower half of canopy than in upper half. Foraged at all levels in mangroves in Torres Strait. Searches among foliage (including dead leaves) of trees and vines, and on and among flowers and fruits, gleaning insects and fruits and probing blossom for nectar (including *Syzgium*); seeks food also on trunks and branches of trees, probing forks and crevices in bark, and, rarely, forages aerially. In Eastern Highlands, not seen to forage in trees with fruits more than 10 mm in diameter. Often hangs upside-down while foraging. At Brown R study site, foraged mostly among flowers (c. 40% of observations) and foliage (29%), at fruits (19%), and occasionally on branches (9%) of rainforest trees; rarely fed aerially (3%); 97% of observations involved gleaning and 3% sallying. Usually unobtrusive, but active and easily observed; can be noisy when foraging. Usually singly, less often in twos (probably pairs) or, occasionally, in small parties of up to eight individuals, some of which family parties of adults and young. Often in same trees as other species, including *Philemon buceroides* and *Myzomela obscura*; also commonly in mixed-species flocks, especially with rufous, brown and black birds, notably Australasian babbler (*Pomatostomus*) and pitohui (*Pitohui*). Can be aggressive towards conspecifics, also aggressive to other species; in flowering trees in Eastern Highlands, commonly displaced similarly sized *X. polygrammus* and *Pycnopygius ixoides*.

Breeding. In New Guinea appears to nest in late dry season to early wet season, and at end of wet season, with breeding noted Aug–Feb and Apr–May (though few records of eggs or nestlings); in Australia reported Sept–Apr (including fledglings Sept, mid-Oct and late Dec, and eggs and nestlings Nov). Nest probably built by female, cup-shaped, woven from strips of bark and bark fibre and leaves, lined with fibre, fine rootlets and fine strips of bark, usually suspended by rim from thin horizontal fork or forks in dense foliage, usually well concealed high in tree or shrub, 3–20 m above ground or water. Clutch 2 eggs; incubation probably by female, both sexes appear to care for and feed chicks and fledglings (once, insects brought to nestling every 2 minutes or so); suggested incubation period c. 15 days and nestling period c. 14 days..

Movements. Resident. In Australia, some may move locally into more open forest in wet season. **Status and Conservation.** Not globally threatened. Abundant and ubiquitous at lower altitudes in New Guinea, and recorded density of 1 bird/ha in lowland rainforest at Brown R; scarcer at higher altitudes, and considered uncommon in surveys in N New Guinea. Common on Torres Strait islands (Boigu and Saibai). Probably uncommon in NE Australia.

173. Kadavu Honeyeater

Xanthotis provocator

French: Méléphage de Kandavu **German:** Goldaugen-Honigfresser **Spanish:** Mielero de la Kandavu
Other common names: Provocator/Yellow-faced Honeyeater, Yellow-faced Xanthotis

Taxonomy. *Ptilotis provocator* E. L. Layard, 1875, Kandavu Island (= Kadavu), Fiji. Genus formerly subsumed in *Meliphaga* by some authors. Present species has in the past been placed in genus *Foulehaio* by some authors; formerly placed also in *Meliphacator* or *Ptilotis*, both now defunct. Monotypic.

Distribution. Kadavu, in S Fiji.

Descriptive notes. 16–21 cm. Rather drab, medium-sized honeyeater with moderately long and gently decurved bill. Top of head and hindneck are drab olive-grey, finely spotted or mottled pale grey on crown, merging to longer sparser fine pale grey streaking on lower hindneck; triangular blackish area extends broadly from lower forehead, over lores, to pter on just in front of eye; yellowish-white lores and anterior cheek merge into narrow yellowish supercilium over and behind eye, meeting greenish-yellow ear-coverts, all combining to form large pale yellowish to golden-yellow area surrounding eye, bordered below by broad blackish malar stripe that extends from base of bill and curves around below ear-coverts, terminating in front of small tuft of yellowish feathers on side of neck; chin and throat pale olive-grey, bordered below by gorget of finely brown-streaked

whitish lanceolate feathers (extends onto side of neck); upperparts drab olive-grey, finely streaked white on mantle, back and scapulars, more diffusely streaked white on rump and uppertail-coverts; upperwing and uppertail darker brownish-grey, fine pale tips on median and greater coverts, fine yellow-olive edges of remiges (diffuse paler panel on folded wing), and diffuse yellow-olive outer edges of tail; underparts below gorget slightly paler olive-grey than upperparts, heavily and broadly streaked white (mid-line almost whitish), and merging to largely whitish vent and undertail-coverts, which faintly tinged or mottled olive-

brown; undertail pale brownish-grey; underwing-coverts pale buff, remiges brownish with pale buff inner edges (appearing largely buff); iris grey-brown to brown, eyering pale yellowish; bill black; legs grey-green. Sexes alike in plumage, male larger than female. Juvenile is like adult but strongly tinged yellowish-olive, with upperwing-coverts and shaft streaks of remiges pale yellowish-olive. **VOICE.** Variety of mellow whistling calls or loud, ringing *Philemon*-like calls, or a jumble of whistles that often starts with strong, ringing "kee-kow" (like that of *Foulehaio carunculatus*).

Habitat. Wide range of habitats, including mature montane and lowland forest, secondary forest, coastal scrub and swamps, mangroves, agricultural land; also towns, villages and urban gardens, and other urban and suburban habitats. Occurs from coast to interior.

Food and Feeding. Poorly described. Mainly nectar, as well as some arthropods (insects and spiders). Regarded as ecological equivalent of *Foulehaio carunculatus* on Kadavu.

Breeding. Poorly known. Three clutches found in Sept, and breeding recorded also in May. Nest a fragile cup, made of fine grasses and rootlets, lined with softer material, including thin wiry grass, with cotton and feathers in base of nest, external diameter 10 cm, depth 6.4 cm, internal diameter 6.4 cm, depth 3.8 cm. Clutch usually (or only) 1 egg (all three clutches found); no information on incubation and nestling periods.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Fiji EBA. Described as very common within tiny global range on single island. No estimates of global population.

Genus PLECTORHYNCHA Gould, 1838

174. Striped Honeyeater

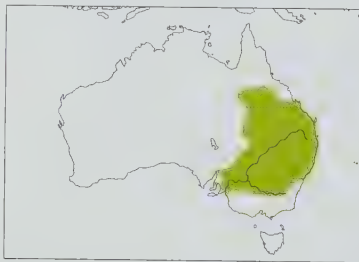

Plectorhyncha lanceolata

French: Méléphage lancéolé **German:** Strichelhonigfresser **Spanish:** Mielero Lanceolado
Other common names: Lanceolated Honeyeater

Taxonomy. *Plectorhyncha lanceolata* Gould, 1838, New South Wales, Australia.

Molecular studies indicate that genus is closely allied to the morphologically dissimilar and monotypic *Grantiella*, both being part of a subclade that includes also *Philemon* and *Xanthotis*. Monotypic.

Distribution. E Australia from C & SE Queensland (mainly S of 20° S) S & SW through inland and NE New South Wales (extending to coast S to about Sydney) to NW Victoria and SE South Australia (E of Yorke Peninsula).

Descriptive notes. 21.5–23.6 cm; male 33–48 g, female 33–45 g. Medium-large honeyeater with short, virtually straight bill and longish tail with slight notch at tip; feathers of head and neck often raised in shaggy crest. Head and neck are white with diagnostic, bold blackish streaking on top and side, isolating diffuse whitish supercilium and lores, and with narrow black moustachial stripe continuing down side of neck and merging with black streaking on sides of lower throat and upper breast; feathers of lower throat and centre of upper breast long and lanceolate; rest of underbody white with fine brown streaking; upperparts brown-grey,

with bold and coarse black-brown streaking on mantle, back and scapulars, and fine diffuse black-brown streaking on rump and uppertail-coverts; narrow greyish-white fringes on median and greater secondary coverts and tertials, narrow whitish edges on other remiges (diffuse pale panel on folded wing); tail has fine white fringes when fresh; undertail dark grey; and underwing dark grey with broad white scaling on coverts; iris brown to black-brown; bill blue-grey, grey-black tip; legs dark blue-grey or grey-black. Sexes alike in plumage, male slightly larger than female. Juvenile is similar to adult, but with shorter, finer and duller, dark brown streaking on head and neck, buff suffusion on top of head (head appears paler overall), finer and duller streaking on mantle, back and scapulars (additionally finely streaked and scaled buff), buff scalloping or mottling on rump and buff wash on uppertail-coverts, upperwing-coverts tipped and fringed buff, tertials tipped buff, edges of remiges tinged cream and suffused buff at tip, and underside white or creamy with only sparse and finer streaking restricted to breast, flanks and undertail-coverts, also bill wholly grey-black; immature similar to adult, but with retained juvenile wing and tail feathers. **VOICE.** Typically noisy, and vocalizes periodically throughout day. Stationary song (usually given while perched) distinctive, a loud, melodious warbling or whistling "chirp, chirp, cherry, cherry", and described as rollicking or bubbling; song phrases also rendered as "chim chee-a-ree" or "chim chim cheere" (duration 1 second). Flight song a sustained, rich phrase, "chee-a-ree chree chirrup" or "chee-a-ree chirrup", rising slightly in pitch and volume, with usually 6–8 phrases sung in succession (total duration c. 7–9 seconds); given in either horizontal or ascending flight. Members of pair duet; duets typically not well synchronized, and usually performed when birds perched within 10 m of each other (but up to 60 m recorded) and more often within 100 m of nest than farther away. Sometimes sings in response to mate's song but not in duet. Calls include "chewee", apparently as contact and given at intervals of 2–3 seconds; a soft

contact warble lasting 5–10 seconds when near or at nest; and a shrill whistling note or short, harsh “zeet” when defending nest.

Habitat. Diverse range of generally tall and open, dry sclerophyll woodlands. Often in eucalypt woodlands, including savanna woodland, riparian woodland, and mallee woodland, especially tall, unburnt, open mallee. Also common in woodlands or scrublands dominated by casuarina, sometimes with mallee eucalypts; and in shrublands and woodlands dominated by cypress-pine (*Callitris*), sometimes mixed with stands of casuarinas, eucalypts or *Eremophila*. Less often in semi-arid and arid *Acacia* shrubland, including mulga (*Acacia aneura*) and lancewood (*Acacia shirleyi*) shrubland; and softwood scrub and woodland, including remnant, dominated by brigalow (*Acacia harpophylla*) or mixed with eucalypts or kurrajong (*Brachychiton*). In coastal and subcoastal regions, often in sclerophyll swamp-forest and woodland of paperbarks (*Melaleuca*) and casuarinas; or heathlands and thickets of casuarina, paperbark or *Banksia*; sometimes in dry sclerophyll forests. Rarely in mangroves. Commonly in modified habitats, such as parks, reserves and gardens of towns or cities, in orchards, vineyards and homestead gardens, and in cleared agricultural land with isolated trees. Wide-ranging, from coasts to arid and semi-arid inland, up to c. 1000 m.

Food and Feeding. Diet includes nectar, seeds, fruits, and invertebrates (mainly insects and their larvae). Forages mostly in foliage and from upper branches of crowns of trees, but occasionally lower and, rarely, on ground. Probes flowers for nectar. Takes invertebrates by gleaning from foliage, twigs and live and dead branches; by probing under loose bark, in crevices in bark, or among woody fruits; and occasionally by sally-striking in air; sometimes while hanging upside-down. Individual gleaning invertebrates from outer foliage of a *Eucalyptus* was observed to take prey to a branch and (unusually for a meliphagid) place item under a foot, then to dismember prey before swallowing. One bird extracted larvae of case moths (Psychidae) by inserting bill into lower end of larval case, which was only point of entry; a few cases were taken to a post and held down by one foot, while larvae removed. Often shy, but noisy. Usually seen singly or in twos; sometimes gregarious, in small parties or flocks of up to twelve individuals; at one site, foraged in loose mobile groups of 2–10 or more, individuals feeding independently at times and moving together at other times. Sometimes forages with other honeyeaters, including *Acanthagenys rufogularis*, *Manorina flavigula*, and *Philemon citreogularis*.

Breeding. Recorded in Aug–Jan, mostly Oct–Nov. Usually nests solitary; co-operative breeding observed occasionally. Nest built by both sexes, a deep, somewhat untidy cup, sometimes bag-shaped, often slightly smaller at opening and with rim running up to points of attachment, usually made of fine grass, sometimes with plant down, hair, rootlets or other vegetation, held together by spider web and egg sacs, plant down, prickly seeds, feathers or wool, which cover exterior, usually lined with dry grass stems, less often with fine rootlets and wool, external diameter 6–10.4 cm, depth 6.5–12.3 cm, internal diameter c. 7–6 cm, depth 6.5–9.6 cm; often Emu (*Dromaius novaehollandiae*) recrires worked into upper portion, which makes nest conspicuous (and material from earlier nests often reused); suspended by rim from thin drooping twigs, foliage or branches, usually in foliage near end of horizontal branch of tall, usually live, shrub, sapling or low tree, 1–12 m (mean 4.5 m) above ground; appears to have nesting association with Grey Butcherbird (*Cracticus torquatus*). Clutch 1–5 eggs, usually 3, only occasionally 1 or 5 (mean of 25 clutches 3.04); incubation by both parents in roughly equal proportions, period probably 15–17 days; chicks brooded and fed by both parents, female of some pairs doing more brooding than male, any helpers present also help to feed chicks, nestling period c. 15 days to 17 or more days; both parents feed fledglings. Nests parasitized by Pallid Cuckoo (*Cuculus pallidus*). From 98 eggs in 35 nests, overall success 0.75 fledged young per nest.

Movements. Appears to be resident over much of range. Some movements recorded, however, even in regions or at sites where normally resident, e.g. occurring at sites where mistletoes (Loranthaceae) or trees in flower. Also sporadic or erratic visitor at some sites, especially inland or at edges of range, where small irruptions sometimes recorded; in New South Wales most isolated records at or near edge of range May–Sept. Scattered records N of main range in Queensland (to W of Townsville), on and E of Great Divide in New South Wales S to about Sydney (largely absent S coast and tablelands), in C & SW Victoria and in SE South Australia (Mt Lofty Ranges and Adelaide Plains) mostly during irruptions. Claims that species is nomadic or partly nomadic based solely on apparently erratic occurrence, and with no data on movements.

Status and Conservation. Not globally threatened. Rather uncommon. No estimates of population. Range has expanded into SE Queensland, mainly since 1960s. At least formerly, considered a pest in orchards at certain times.

Genus *GRANTIELLA* Mathews, 1911

175. Painted Honeyeater

Grantiella picta

French: Méléphage peint **German:** Granthonigfresser **Spanish:** Mielero Pintado

Taxonomy. *Entomophila picta* Gould, 1838, New South Wales, Australia. Molecular studies indicate that genus is closely allied to the morphologically dissimilar and monotypic *Plectorhyncha*, both being part of a subclade that includes also *Philemon* and *Xanthotis*. Genus has in the past been subsumed in *Conopophila*. Monotypic.

Distribution. N & E Australia: CE Northern Territory (sparse) and Queensland W of Great Divide and S of c. 20° S (though few records in SW S, on and W of Great Divide, to N Victoria.

Descriptive notes. 14–15 cm; three males 20–25–20 g, one female 18 g. Distinctive medium-small honeyeater with short, gently decurved bill and short tail. Male is strongly pied, mostly black above (slightly duller on rump, uppertail-coverts and upperside) and white below, with black hood sharply demarcated from white throat, small white patch on rear ear-coverts, and sparse blackish streaks or spots on flanks, breast and belly; rump and uppertail-coverts also variably mottled or scaled with brown, sometimes white band across rump; blackish upperside boddy marked with broad pale yellow margins on median and greater secondary coverts and bright yellow outer edges on greater primary coverts and remiges (bright yellow panel on folded wing); uppertail appears black with

yellow sides and fine white tip (when spread, shows obvious white tip and yellow panels in sides); underwing white, dark mottling on outer coverts, reflective blackish-brown trailing edge and tip; undertail mostly white with black sides; iris red-brown, often dark; bill and gape pink, brownish tip of bill; legs dark grey. Female is like male but somewhat smaller, with upperparts and chin duller, brownish-black, olive-brown tinge on rump, and slightly darker blackish face and duller top of head. Juvenile is like female, but upperparts and chin much paler, brown to grey-brown, with pale mottling or scaling on rump and uppertail-coverts, paler yellow to off-white edges on upperside-coverts and tertials (and usually pinkish-buff fringes at tips), and edges of remiges (and panel on folded wing) slightly paler yellow, also bill greyish-horn (not pink), iris greyish-brown, and legs greenish-grey. **VOICE.** Noisy. Song the most common vocalization, given from perches and in display-flight, a highly distinctive, repeated loud two-syllable piping “geor-gie” or “georg-ééé” or “sue-see”, with second syllable higher-pitched; also siren-like variant, “see-sue”, “wee-oo” or “fee-oo”, and occasionally other variants of main song. Series of “chur” phrases, repeated 4–48 times, often given at change-over at nest; phrase of female hoarser, more throaty and less audible than that of male. Has low-intensity and high-intensity alarm calls, including plaintive whistle. Other calls include frequent disyllabic “chee-haw”, in which second syllable lower-pitched; low twittering notes during construction of nest; and double “chew-it” during incubation and early part of brooding by assumed female. Said to give loud but undescribed single note, piping and soft chatters and purring notes, soft “tweet” calls and other soft calls.

Habitat. In all habitats, strongly associated with presence of mistletoes, e.g. drooping (*Amyema pendulum*), box (*Amyema miquelii*), needle-leaf (*Amyema cambagei*), grey (*Amyema quandang*) and wire-leaf mistletoes (*Amyema preissii*). Mainly in box–ironbark eucalypt woodlands and forests on inland foothills of Great Divide, dominated by such species as red ironbark (*Eucalyptus tricarpa*), mugga (*Eucalyptus sideroxylon*) and yellow box (*Eucalyptus melliodora*); box eucalypt–casuarina woodlands, especially those dominated by yellow gum (*Eucalyptus leucocylon*) with buloke (*Allocasuarina leuhmannii*) or belah (*Casuarina cristata*); riparian forests of river sheoak (*Casuarina cunninghamiana*); and in scattered eucalypts or remnant patches of woodland or forest in farmland. Less often in patches of *Acacia* with mistletoes, in woodlands dominated by cypress-pine (*Callitris*), woodlands of river red gum (*Eucalyptus camaldulensis*) and black box (*Eucalyptus largiflorens*), in mallee woodland, and in paperbark (*Melaleuca*) associations. Sometimes in urban parks and gardens, especially with large eucalypts. In study of irruption in woodland dominated by brigalow (*Acacia harpophylla*), gidgee (*Acacia oswaldi*), rosewood (*Allocryon oleofolium*) and white cypress-pine (*Callitris glaucochylla*) in N New South Wales, woodland in which this species was found had significantly more mature trees, greater canopy cover and more mistletoes per tree and per unit area than did sites not occupied.

Food and Feeding. Diet mostly fruit and nectar of mistletoes, as well as other fruit, and nectar from flowering eucalypts and other plants; also invertebrates (insects, spiders). Usually forages in canopy of trees, especially among flowering and fruiting mistletoe. Invertebrates gleaned from foliage or branches, also taken by sally-striking in air. Forages singly, in pairs or in small parties of up to six individuals; occasionally in larger groups, e.g. in NE Victoria 100 or more in small groups dispersed through forest.

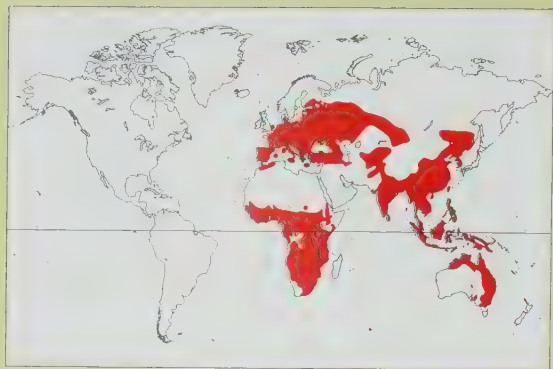

Breeding. Timing may depend on availability of mistletoe fruit; recorded Aug–Feb, apparently starting on average later farther S; claim of eggs in Northern Territory in Mar; in Victoria usually two broods each year, in Oct–Nov and Jan–Feb, but only one brood if fruiting season poor. Pairs tend to nest close together, and possibly loosely colonial, but distance between nests varies; will nest solitary, but some solitary attempts known to have failed or been abandoned; study required to determine success of solitary nests and group-nesting. Both sexes collect nesting material and both build, often together; nest usually a strong but thin cup (some more substantial) made of grass or fine rootlets, occasionally with twigs, flowers, bark or fibres, and bound together and attached to nest plant with spider web (which may sometimes form much of nest), external diameter 6.4–7.6 cm, depth 3.8–5.1 cm, internal diameter 5.1 cm, depth 4.4 cm; attached by rim to pendulous foliage and drooping branchlets in outer part of tree (mainly eucalypt or casuarina), often one with mistletoes. 18 nests were 2–15 m (mean 7.2 m) above ground, but up 19.5 m recorded; usually returns each year to same or nearby tree to nest, and in one case nests built in almost identical position in same tree for 5 years in succession. Clutch usually 2 eggs, occasionally 1 or 3; incubation by both sexes, also male said to feed incubating female constantly, period at least 13 days or 14–15 days; chicks brooded by both parents, mostly by female, also fed by both, nestling period once 20 days; both parents feed fledglings.

Movements. Generally considered a N–S migrant, being a non-breeding winter visitor N of c. 26° S. In S of range, most records New South Wales between Sept–Oct and Mar–Apr and in Victoria between late Sept/early Oct and early Dec (occasional records to Feb–early Apr); in N, most records in Northern Territory May–Aug (majority Jun–Jul) and most in N Queensland Jun–Sept. Analysis of data for E Australia found no conclusive evidence of any movements. Irregular visitor at some sites, and sometimes considered nomadic, although extent of movements involved and context in wider patterns of movements not known. Presence in an area, and movements, sometimes linked with fruiting of mistletoe. Males said to arrive in breeding areas at least two weeks before females, and young said to migrate with parents. Vagrant in E South Australia, although no recent records; single record in N Western Australia (at Bell Creek, in W Kimberley), in mid-May 2002.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally uncommon and sparsely distributed. Total population possibly c. 50,000 birds. Once recorded as breeding at density of 0.03 birds/ha. Thought to have undergone long-term decline, likely to have been caused or accelerated by clearing or thinning of trees for agriculture, and lack of tree regeneration because of grazing, or overgrazing, by introduced herbivores such as livestock and rabbits (*Oryctolagus*). Much habitat used for breeding, in S of range, has become degraded, and species has declined in numbers in CN Victoria, W New South Wales and probably NC Queensland; also no recent records from S South Australia. Preference for mature trees with greater canopy cover, as shown by study in brigalow woodlands of N New South Wales, indicates that protection of sites with these habitat characteristics likely to be important for the survival of this species.

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family ORIOLIDAE (ORIOLES)

- Medium-sized, robust passerines with relatively strong bill; many species very colourful in yellow to golden and black.
- 17.5–32 cm.

- Old World.
- Woodland, forest and parklands.
- 2 genera, 30 species, 92 taxa.
- 3 species threatened; none extinct since 1600.

Systematics

The orioles and figbirds form a small and well-defined family of highly arboreal, medium-sized birds inhabiting woodlands, forests and parklands of the warmer parts of the Old World, mainly in Africa and tropical southern Asia eastwards through Wallacea and New Guinea to Australia. Different authors have recognized between 25 and 30 species in the family, and with differing species limits within this range. In the present treatment, Oriolidae comprises 30 species in two genera: *Sphecotheres*, containing the figbirds, and *Oriolus*, with the orioles. Figbirds are distinguished on the basis of the bare red skin around the eye and their colonial nesting habits. Among the orioles proper, some early taxonomists separated a sombre-coloured group of Australasian species, which they placed in the genus *Mimeta*, from the generally brightly coloured Afro-Asian species, which constituted the genus *Oriolus*, but R. B. Sharpe, in his 1877 review of the family, combined them all in *Oriolus*. This arrangement was continued in a 1923 review by R. Meinertzhagen, who pointed out that the only criterion for retaining *Mimeta* would be that the species involved lacked the brilliant colours of adult *Oriolus*; in all other respects, however, the two groups are closely similar. Meinertzhagen also reasoned that the family might be Australo-Papuan in origin, rather than, as had formerly been assumed, Oriental. His argument was based on the fact that adults of the former region's *Mimeta* group retained a striped plumage like that of juveniles of the brightly coloured Afro-Asian species, and the fact that the genus *Sphecotheres* is confined to eastern Indonesia, New Guinea and Australia. Meinertzhagen envisaged two distinct branches arising from Australasia. The first involved the two maroon species, namely the Maroon Oriole (*Oriolus trailii*) and the Black-and-crimson Oriole (*Oriolus cruentus*), in Southeast Asia; this branch, linked to *Mimeta*, he thought, by the Black Oriole (*Oriolus hosii*), did not spread to the Palearctic or Africa. The second branch produced the bright black-and-yellow orioles, linked to *Mimeta* by the Isabela Oriole (*Oriolus isabellae*) and the Philippine Oriole (*Oriolus steerii*), over the rest of Eurasia and Africa.

Traditionally, the Oriolidae were considered to be most closely related to the drongos (Dicuridae), the crows (Corvidae), the leafbirds (Chloropseidae) and the fairy-bluebirds (Irenidae). On the basis of evidence obtained in analyses of DNA–DNA hybridization, however, C. G. Sibley and J. E. Ahlquist found the orioles' immediate closest relatives to be the cuckoo-shrikes

(Campephagidae). These authors placed the orioles and cuckoo-shrikes together in a tribe, the Oriolini, in the subfamily Corvinae, within their much-expanded family Corvidae. Although the link between the orioles and the cuckoo-shrikes is corroborated by the results of protein studies and some similarities in osteological traits, other morphological differences suggest that the retaining of Oriolidae and Campephagidae as separate families is the preferable course of action. Although Sibley and Ahlquist's family Corvidae also includes the drongos, DNA–DNA hybridization does not support a close relationship between the drongos and the orioles. More recent sequencing of nuclear genes reveals the leafbirds and the fairy-bluebirds to be even more remote from the orioles. Thus, although taxonomic syntheses based on the sequencing of both mitochondrial and nuclear genes have pro-

Figbirds (*Sphecotheres*) differ from orioles (*Oriolus*) in having bare skin around the eye and by breeding colonially. Current taxonomy considers Oriolidae to comprise 30 species, whereas some previous authors identified as few as 25. The figbirds have been notably affected by this recent splitting, as the **Timor Figbird**, endemic to two islands in the Lesser Sundas, was previously considered conspecific with both its congeners, so that just a single figbird species was recognized.

[*Sphecotheres viridis*, W Timor, Lesser Sundas. Photo: Morten Strange]

Stocky, medium-sized passerines, the oriolids are rather long-winged and short-legged. In terms of proportions, figbirds differ from orioles by having a longer tail and shorter bill. Some members of the family show sexual dichromatism. In about half of the orioles and all the figbirds, the female is considerably drabber in plumage than the male. In the **Australasian Figbird**, the male (right) is brightly coloured, whereas the female (left) is brown above and heavily streaked below.

vided a finer and perhaps more reliable resolution of some parts of the oscine tree, as shown by, for example, the 2003 study by P. G. P. Ericson and U. S. Johansson, they have not so far directly affected the lower-level inter-familial relationships of the orioles as suggested by Sibley and Ahlquist in 1990.

The position of the Madagascan genus *Tylas* is of some interest. It has been suggested that this genus, which contains a single species, *Tylas eduardi*, might be closely related to the Oriolidae. Current opinion, however, is that it is a vanga, and it is generally therefore placed in the Vangidae, a family confined to Madagascar and the nearby Comoro Islands. Nevertheless, the true systematic position of the *Tylas* Vanga merits further study.

Molecular-genetic techniques have not yet been used as a means of investigating species limits within the family Oriolidae, and these still rely on conventional characters such as osteology,

plumage and voice. Although the genus *Oriolus* appears remarkably homogeneous, with no need for subdivision, as was recognized by Sharpe, Meinertzhagen and, most recently, J. C. Greenway in J. L. Peters's *Check-list of Birds of the World*, attempts have nevertheless been made at one time or another to introduce some substructuring, by proposing alternative genera or subgenera in which to group similar species. Five such suggestions have been made. The first of these involves the original Australasian genus *Mimeta*, erected by N. A. Vigors and T. Horsfield in 1827, and comprising dull brown to olive-green species with striped underparts. This name has been used to group the Green Oriole (*Oriolus flavocinctus*) with the Brown (*Oriolus szalayii*), Dusky-brown (*Oriolus phaeochromus*), Grey-collared (*Oriolus forsteni*), Black-eared (*Oriolus bouroensis*), Olive-brown (*Oriolus melanotis*) and Olive-backed Orioles (*Oriolus sagittatus*). These last six were considered by Sibley and Monroe and by R. Schodde and I. J. Mason to form a superspecies.

The alternative genus *Xanthonotus*, originally described by C. L. Bonaparte in 1854, has been used to group the Dark-throated Oriole (*Oriolus xanthonotus*), the Philippine Oriole and the Isabela Oriole, the first two of which were considered by Sibley and Monroe to be sister-species. The subspecies *albiloris* of the Philippine Oriole has sometimes been elevated to the rank of a full species, but in other treatments the Philippine Oriole, including *albiloris*, has been considered a subspecies of the Dark-throated Oriole.

C. M. N. White and M. D. Bruce, in their 1986 checklist of Wallacea, considered the Eurasian Golden Oriole (*Oriolus oriolus*), African Golden Oriole (*Oriolus auratus*), Slender-billed Oriole (*Oriolus tenuirostris*) and Black-naped Oriole (*Oriolus chinensis*), the so-called "yellow-headed group", to constitute a superspecies, to which the Indian Golden Oriole (*Oriolus kundoo*), now separated from the Eurasian species, can be added. Four years later, however, Sibley and B. L. Monroe treated these taxa as comprising two sets of sister-species: *O. oriolus*, with *kundoo* as a subspecies, and *O. auratus* forming one set; the other consisting of *O. chinensis* and *O. tenuirostris*.

In the Afrotropics, the "African black-headed group", comprising the Green-headed (*Oriolus chlorocephalus*), Sao Tome (*Oriolus crassirostris*), Western Black-headed (*Oriolus brachyrhynchus*), Ethiopian Black-headed (*Oriolus monacha*), Mountain (*Oriolus percivali*), Eastern Black-headed (*Oriolus larvatus*) and Black-winged Orioles (*Oriolus nigripennis*), could be considered to belong to the alternative genus *Baruffius*, created by Bonaparte in 1854. Sibley and Monroe regarded the West-

Among males and also the females of some species, typical oriole plumage comprises large areas of vivid colour. Two species groups inhabiting different continents complete this startling effect with a glossy black or dark head. The "African black-headed group" comprises seven species, including the **Ethiopian Black-headed Oriole**. In this group, female plumage is similar to that of the male. There is a greater degree of sexual dichromatism in the four species that form the "Asian black-headed group" of orioles.

Ferdinand]

ern Black-headed and Ethiopian Black-headed Orioles as sister-species, and the Eastern Black-headed and Mountain Orioles likewise to be sister to each other.

Finally, the alternative genus *Analcipus*, created by W. Swainson in 1832, has been used to accommodate the Black Oriole, Black-and-crimson Oriole, Maroon Oriole and Silver Oriole (*Oriolus mellianus*). These, together with the Black-hooded Oriole (*Oriolus xanthornus*), have been referred to as the "Asian black-

headed group". Within this group, the Maroon and Silver Orioles were considered sister-species by Sibley and Monroe.

As it is not clear to what extent plumage characteristics among orioles, on which much of the above grouping rests, carry a strong phylogenetic signal, we cannot be confident that such substructuring accurately reflects evolutionary relationships within the oriole family tree. Given also that some species, such as the Black-naped Oriole, are undoubtedly polyphyletic as presently constituted, a molecular-genetic reappraisal of the Oriolidae is much needed.

Schodde and Mason, in 1999, proposed that the genus *Sphecotheres* should be placed before *Oriolus* in the systematic sequence, because they regard *Sphecotheres* as the ancestral taxon. This is the practice currently adopted.

Morphological Aspects

Orioles and figbirds are medium-sized, robust passerines 20–30 cm in length. The sexes are of similar size, although the female is usually slightly smaller than the male. Orioles have a slightly decurved and finely hooked bill which is about equal in length to the head. It varies, however, from being long and slender, as with the Slender-billed Oriole, to robust, deep and broad, as in the Sao Tome Oriole and some races of the Black-naped Oriole, or rather short and like that of a bulbul (Pycnonotidae), as in the Western Black-headed Oriole. Figbirds differ from orioles proper in having a very short bill. In the Eurasian Golden Oriole, the bill of the juvenile is dark reddish-brown, changing to pale red in adults; likewise, the juvenile's iris is light brown and usually becomes progressively redder with age. Orioles have relatively large, long and pointed wings with ten primaries, the outermost, P10, being about half the length of the adjacent one (P9), with primary P8 the longest. The tail is square, short to medium length, and has twelve rectrices. The tarsi are relatively short but strong, and the feet are also short but rather weak; they are apparently not used in feeding.

Many species of oriole are colourful, at least in the adult male plumage, which is often patterned in brilliant golden-yellow and black colours. The family name may derive from the Old French *oriol*, which may, in turn, have come from the Latin *aureolus*,

A group of Australasian orioles have dull olive-brown plumage for a quite remarkable reason: they mimic the particular species of friarbird (Philemon) with which they share their range and habitat. This imitation presumably originated as a mechanism of reducing the threat of being attacked. New Guinea's **Brown Oriole** is thus very similar in plumage to the Helmeted Friarbird (*P. buceroides*) and even imitates the latter's vocalizations. Amazingly, the Brown Oriole is itself mimicked by a smaller species, the Streak-headed Honeyeater (*Pycnopygius stictocephalus*), which, like the friarbirds, belongs to the family Meliphagidae.

[*Oriolus szalayi*, Port Moresby, SE New Guinea. Photo: William S. Peckover]

Most oriole species are brightly coloured. The golden-yellow that is the base colour of many can, perhaps surprisingly, offer the bird concealment in its sunny woodland habitat. Among some Asian orioles, however, the yellow is replaced by silver, crimson or maroon, as in the case of the **Maroon Oriole**. Such species have a grey or bluish bill, whereas the yellow ones have a pink or red bill. Juvenile orioles tend to resemble the respective female, but subsequent development towards mature adult plumage remains poorly known in many species.

[*Oriolus traillii ardens*, Wu Lai, Taiwan. Photo: Penshing Liao]

meaning "golden", or it may be just an onomatopoeic rendition of a common oriole call (see Voice), or it could be due to both. It was applied originally to the Eurasian Golden Oriole, but the males of many other species in the family are also mostly golden-yellow with black wings, the African Golden Oriole being a good example, although some Oriental species have the yellow replaced by crimson or silvery white. Those species having yellow in the plumage possess a dull red or pink bill, whereas those with red in the plumage have a horn-coloured or bluish bill. Figbirds are much duller in plumage, being predominantly dull yellow, green, brown and grey or white, with a black or brownish bill. Within the Oriolidae, there are occasional documented records of melanistic individuals or individuals with other colour aberrations.

Although the adult plumages of male and female orioles are mostly well known, the sequence of immature plumages as young birds moult from juvenile to adult is not. Among species in which the sexes differ strongly in adult coloration, sexual differences usually become apparent after the second moult. In general, the immature plumage of females can be expected to resemble a duller version of the adult female, but in the case of males of such species, or with orioles in which adults of both sexes are brightly coloured, an immature may pass through a more complex sequence, especially if sexual maturity is delayed. For many of the oriole species this has been poorly recorded, and further research is required. Adult orioles apparently moult once per year.

Orioles and figbirds vary in the degree of sexual dichromatism exhibited. Some species are distinctly dichromatic, with the female quite different from and much less brightly coloured than the male. Examples include the Eurasian Golden Oriole and the African Golden Oriole, the females of which retain an olive-green, streaked plumage like that of an immature, although, on rare occasions, females strongly resemble the males. In about half of the species, however, the female resembles the male or is only slightly duller. This is so in the "African black-headed group", which comprises the Eastern Black-headed, Western Black-headed and Ethiopian Black-headed Orioles, the Mountain Oriole and the Black-winged Oriole; also included with these species are the Green-headed Oriole, which has the black pigment of the head replaced by green, and the island endemic, the Sao Tome Oriole, which resembles a "washed-out" version of the mainland species. The "Asian black-headed group" includes four species,

the Black, Black-and-crimson, Maroon and Silver Orioles, which exhibit no yellow but, instead, have this colour substituted by red, brown or silver. These species are sexually dichromatic, although the degree to which this is expressed varies. Uniquely, the Black-and-crimson Oriole has two subspecies which are strongly dichromatic while the other two are apparently monochromatic. Several Australasian species, however, lack bright coloration in both sexes and are generally greenish above and

Preening is an essential activity for all birds. Stretching a wing enables this female **Eurasian Golden Oriole** to repair any remiges where the barbules have become displaced, reducing flight efficiency. Birds also preen in order to waterproof their feathers: coating the bill in oil from the uropygial gland, birds smear this waterproofing agent all over their feathers. It is also believed that uropygial oil serves to repel parasites by dint of having antifungal and antiparasitic characteristics.

[*Oriolus oriolus*, Hungary.]

Photo: Markus Varesvuo

Bathing is an important routine, helping to rid the feathers of parasites. Most birds wishing to bathe approach the water source from ground level. The **Eurasian Golden Oriole**, however, frequently bathes by plummeting steeply from a nearby perch, splashing briefly into the water, and then heading rapidly to a tree or bush. This oriole also behaves like swallows (*Hirundinidae*) by gliding over water and briefly dipping in its underparts.

[*Oriolus oriolus*, Dauka, Oman.]

Photo: Hanne & Jens Eriksen

streaked below, resembling the females and immatures of the African and Asian species that are strongly dichromatic. In this respect they are similar to the figbirds, both sexes of which are also greenish above and streaked below, the most conspicuous sexual dichromatism being in the colour of the bare skin around the eye, which is red in the male and bluish-grey in the female.

The drab brown or olive-green coloration of a number of Australasian oriole species may be unimpressive in itself, but it is remarkable in that it closely mimics the plumages of friarbird (*Philemon*) species, which have ranges coinciding with those of the orioles themselves. The mimicry in coloration includes the possession by the orioles of black-feathered areas that match areas of black bare facial skin on the friarbirds, and the similarities are so close that even specimens held in the hand may be confused. This plumage mimicry is reinforced by similarities in posture, movements and flight, as well as by vocal mimicry in two species, so that orioles and friarbirds may be even harder to distinguish in the field, although the friarbirds belong to a different family, the honeyeaters (Meliphagidae). Thus, in New Guinea, the Brown Oriole is similar visually and also vocally to the Helmeted Friarbird (*Philemon buceroides*), although it is streaky below and lacks the friarbird's bill knob. The Dusky-brown Oriole on Halmahera is a close visual mimic of the Dusky Friarbird (*Philemon fuscicapillus*) and difficult to distinguish in the field, and on Seram the Grey-collared Oriole is virtually identical to the Seram Friarbird (*Philemon subcorniculatus*). The two subspecies of the Black-eared Oriole, one on Buru and the other in the Tanimbar Islands, are each visually very similar to the respective island races of the Black-faced Friarbird (*Philemon moluccensis*) and are said also to be vocal mimics. On Wetar, the female of the local race *finschi* of the Olive-brown Oriole is quite similar to the local Helmeted Friarbird but the male is less so, while on Timor, where the nominate race of this oriole occurs, the female is again quite similar to the Helmeted Friarbird but the male is not. In Australia, however, where both the Olive-backed Oriole and the Green Oriole overlap in range with the Helmeted Friarbird, there is no mimicry.

It seems clear that the orioles mimic the friarbirds, rather than *vice versa*. The brown plumage and black facial skin are shared by all except one species of friarbird and by many other meliphagids, but the combination of brown plumage and black

facial feather patches is unique among orioles. Furthermore, sister-taxa with identical plumage in the same friarbird superspecies occur on many islands where the mimicking orioles do not, yet the mimetic orioles are virtually confined to islands with friarbirds. A further intriguing fact is that, the greater the size disparity between friarbird and oriole, the more perfect is the mimicry. Orioles in this superspecies are rather uniform in body mass, whereas the friarbirds vary from oriole-sized to roughly twice this. The Seram Friarbird is the largest and is approximately 78% heavier than the Grey-collared Oriole, which is an almost perfect mimic of it. The friarbirds on Halmahera, Buru and Tanimbar are about 50% larger than the Dusky-brown Oriole and the two races of the Black-eared Oriole, respectively, and the mimicry of these last is close but not perfect. In New Guinea and on Wetar, the friarbirds are about 39% heavier than the Brown and Olive-brown Orioles, respectively, and the mimicry is even less good. On Timor, where the friarbird is only some 13% larger than the Olive-brown Oriole, the mimicry is fair in the female but absent in the male, and it is lacking altogether in both sexes of the Olive-backed and Green Orioles in Australia, where the local friarbirds also average only 12% larger. A further twist to the story is that the Brown Oriole in New Guinea is itself closely mimicked, both visually and vocally, by another meliphagid less than half its size, the Streak-headed Honeyeater (*Pycnopygius stictocephalus*).

These size relationships between models and mimics suggest that smaller birds are mimicking larger ones, rather than its being a case of Batesian mimicry, in which palatable orioles may avoid predation by mimicking a distasteful friarbird model. There is no evidence that friarbirds are distasteful, nor would Batesian mimicry explain why another honeyeater would mimic an oriole. J. M. Diamond has plausibly suggested that the frequent incidence of attacks among orioles, friarbirds and other honeyeaters might provide a strong selective force for the evolution of size-dependent mimicry. These birds have similar habitat preferences and regularly feed together in the same flowering and fruiting trees, exhibiting a broad overlap in their diets of insects, fruit and nectar. There is a great amount of fighting within these feeding assemblages, with a dominance hierarchy based on size and aggressiveness, the larger birds, friarbirds especially, being more combative and more successful. Nevertheless, Diamond, during his studies in New Guinea, never observed an attack by a Helmeted Friarbird on a Brown Oriole, nor an attack by a Brown Oriole on a Streak-headed Honeyeater, despite the fact that these regularly fed within a few metres of each other and frequently attacked other species. In north-east Australia, however, he saw the same friarbird species attack and drive off the smaller non-mimetic Green Oriole, and in south-east Australia the non-mimetic Olive-backed Oriole stands its ground when attacked by the similar-sized Noisy Friarbird (*Philemon corniculatus*), and either species may win or lose a fight. Diamond's suggestion is that mimics, by convergence in appearance, escape attack by larger models that might otherwise drive them away; and, the greater the size disparity between oriole and friarbird, the more perfect the mimicry had to be for the oriole to protect itself against an increasingly large aggressor.

Although the Australian populations of the Olive-backed Oriole do not mimic friarbirds, they may mimic the Australasian Figbird (*Sphecotheres vieillotii*). The plumage of both sexes of the former is very similar to that of the female figbird, and the oriole often feeds with figbird flocks and may nest close to figbird breeding colonies. The Olive-backed Oriole's behaviour is secretive in the presence of figbirds, which ignore it, whereas the presence of other species usually elicits an aggressive response.

Habitat

Orioles are primarily canopy feeders (see General Habits). Almost all members of the family have been recorded in primary forest habitats of various kinds: dry, closed-canopy African woodlands, evergreen and semi-evergreen broadleaf forests, including monsoon forest, damp highland and moss forests, eucalypt (*Eucalyptus*) woodland, and deciduous and coniferous forests, as well as mixed forests such as pine-oak (*Pinus-Quercus*) forest.

Many orioles are renowned for their rich, mellifluous songs, and the liquid, fluting or whistling quality of these is immediately recognizable as emanating from an oriole. Their vocalizations are, however, not always so easy on the human ear. Most species, the **Maroon Oriole** among them, also have rather harsh, nasal or growling calls, in addition to a distinctly feline "miaow". In contrast to the orioles, the vocal repertoire of figbirds is somewhat impoverished, comprising rather tuneless whistles, chirps or trills.

As the English name of the genus suggests, figbirds are primarily frugivorous. Inevitably, figs (*Ficus*) form an important part of the diet of the **Australasian Figbird** (above male, below female), but this species also consumes fruits from a wide range of trees and shrubs. Favoured plant genera or species include raspberries (*Rubus*), mulberries (*Morus*), native cherries (*Exocarpus cupressiformis*), guavas (*Psidium*) and cultivated bananas (*Musa*). Australasian Figbirds are active and noisy foragers, usually feeding in pairs but also, occasionally, alone. Outside the breeding season, their gregarious nature means that they frequently congregate in flocks of more than 100 individuals, moving noisily around their forest habitat in search of fruiting trees. Australasian Figbirds also readily take advantage of other sources of food offered by shrubs and trees, alternately eating seeds and sipping nectar, depending on the season.

While orioles have a rather varied diet, they are primarily frugivorous. The **Olive-backed Oriole** is typical, seeking out fruits and berries as varied as olives (*Olea*), figs (*Ficus*), camphor laurel (*Cinnamomum camphora*) and white cedar (*Melia azedarach*). This species is also one of several orioles attracted to commercial orchards, raiding grape (*Vitis*), cherry (*Prunus*) and paw-paw (*Asimina*) plots. Not surprisingly, this sometimes results in persecution by fruit farmers.

[*Oriolus sagittatus sagittatus*, near Bugaldie, New South Wales, Australia.
Photo: W. R. Taylor/Ardea]

Nevertheless, with the exception of the globally threatened and Near-threatened species (see Status and Conservation), which appear to be particularly dependent on large undisturbed tracts of closed-canopy forest, most orioles seem to prefer semi-open woodland habitats over completely closed forests, even when taking into consideration the possibility of observer bias due to the fact that birds are more easily observed in open habitats. These open woodland habitats can also be of various kinds, although they are structurally rather similar to one another. Thus, 20 oriole species have been recorded in forest edges, including treefall gaps and small overgrown clearings, 19 in relatively mature second growth, 16 in semi-open woodlands, 15 in cultivated areas with

large trees, 13 in tall riverine vegetation such as gallery forest, twelve in plantations, twelve in gardens, nine in parks, five in windbreaks and avenue trees, five in groves and five in orchards. Other, similarly open habitats include bushes, scrub and thickets, in which eleven oriolids have been recorded, mangroves, with ten species, swamp-forests, with five, and bamboo forests, in which three have been found. In a particularly comprehensive study, S. Baumann monitored the movements of breeding Eurasian Golden Orioles in northern Germany. Using telemetry, she found that movements varied strongly from one breeding pair to another depending on habitat geometry, time of the breeding season and, concurrently, food supplies. Forested habitats were clearly preferred, but tree plantations, parks, gardens and isolated groups of trees, such as avenue trees, were also popular, while treeless habitats were almost completely avoided.

Although orioles are usually bound to tree-dominated habitats, they do nevertheless sometimes exploit other habitats opportunistically. In particular, the Eurasian Golden and Indian Golden Orioles are found in open deserts and high mountain regions during migration. While the Eurasian Golden Oriole does no more than rest on stopover at Saharan oases while on passage through Africa, the Indian Golden Oriole breeds in such places, for example oasis plantations in the Kyzyl-Kum Desert, south-east of the Aral Sea. The Eurasian Golden Oriole also forages in treeless heath and among sand dunes on almost treeless islands, using the few trees present for breeding only. Thus, the breeding requirements of these species may sometimes be as simple as a tree with a suitably shaded forked branch for nesting and sufficient invertebrate food available in the foliage or on the ground.

General Habits

Orioles are highly arboreal, generally foraging secretively alone or in pairs. Despite the conspicuous plumage of most of the species, orioles are usually hard to see against a leafy forest background dappled by the sun's rays, and they seem deliberately to hide from the observer, although their characteristic calls (see Voice) reveal their presence. Even in flight, orioles may be inconspicuous. The typical flight pattern is swift, silent and undulating, as the bird closes its wings at regular intervals, in the manner of a woodpecker (*Picidae*). They have a powerful but somewhat irregular wingbeat, reaching average speeds of 40–47 km/h, and a male can achieve up to 70 km/h when chasing

Whilst fruits and berries comprise much of the diet of orioles, invertebrates provide a significant proportion too, particularly in the case of migrating and wintering **Eurasian Golden Orioles**. This bird has just caught a grasshopper (*Orthoptera*). Amidst a wide variety of invertebrates taken by Eurasian Golden Orioles are earthworms (*Oligochaeta*), dragonflies (*Odonata*), cicadas (*Cicadidae*) and hoverflies (*Syrphidae*). The protein provided by invertebrate larvae, in particular, forms the major component of the diet of newly hatched Eurasian Golden Oriole nestlings.

[*Oriolus oriolus*, Razhdavitsa, Kyustendil, Bulgaria.
Photo: Iva Hristova]

While oriolids tend to spend the majority of their time foraging in the middle and upper strata of trees, the occasional abundance of aerial insects can sometimes prove attractive too. Both orioles and figbirds willingly leave the confines of the canopy to flycatch for winged termites (Isoptera) and the like. This **Australasian Figbird** is seen in mid-sally; once successful, it will return to a secluded perch to consume its catch.

[*Sphecotheres vieilloti*
vieilloti,
near Brisbane, SE
Queensland, Australia.
Photo: Brian J. Coates]

Like its congeners, the **Black-naped Oriole** takes large numbers of invertebrates, such as this small spider (Araneae). Small vertebrates including nestlings are also readily taken. This species mainly forages in the canopy, where it hops, climbs or makes short flights to investigate sites that might harbour prey. Orioles use both eyes and ears to locate insects, which they glean or pluck from their hiding places. On occasion, the pursuit of insects takes the Black-naped Oriole into the lower strata. Larger insects are prepared for consumption by being brushed or wiped against the perch.

another male. In their favoured, tree-dominated habitats they will typically fly from treetop to treetop, never staying in the open for long. Before landing on a perch, they typically sweep upwards with half-opened wings. Orioles can hover for short periods, with an upright body posture and fast-beating wings, looking not unlike a miniature kestrel (*Falco*), in order to observe or catch a food item or when building a nest. Figbirds, on the other hand, are gregarious and travel in noisy flocks of up to 100 or more individuals. A feeding flock may remain in a fruiting tree until it is virtually stripped clean, the birds even hanging upside-down on the ends of twigs to reach the last fruits. Many oriole species, especially in the tropics, occasionally gather in small groups in fruiting or flowering trees, and regularly join marauding mixed-species flocks in the search for food; these mixed flocks can comprise a dozen or more different bird species. Likewise, up to ten individuals may congregate in a small area wherever caterpillar densities are high. Although orioles generally sleep solitarily, evening roosts can at times attract dozens or even hundreds of individuals to the same place. Usually, however, individuals or pairs keep away from each other in widely spaced feeding territories, with younger individuals floating in and out of these territories. The Eurasian Golden Oriole, for example, has an average feeding range of about 40 ha, but this varies from 7 ha to 110 ha, while defended territories around the nest are much smaller, at about 1.3 ha, ranging from 0.7 ha to 2.3 ha.

Territorial advertisement and defence against conspecifics involve calls and songs (see Voice), most singing taking place in the morning and evening from exposed and regularly used perches high in the tree canopy. The calling frequency decreases in bad weather and also after the young have hatched. In order to heighten the threat against an intruder, the Eurasian Golden Oriole turns from side to side and ruffles its neck feathers while giving a more varied song than usual, and with increased volume, speed and intensity. It may then resort to an aggressive stance, with the wings held open, the tail fanned and the head stretched forward, aided by short, loud calls, wing-beating and beak-snapping, or it may even hover in front of the intruder. Finally, chases and physical attack ensue, and these can, in rare instances, lead to injury or death through collision in the air or impact with the ground resulting from the birds interlocking their feet.

With their often brightly coloured plumage but self-concealing habits, it is difficult to know how vulnerable adult orioles

may be to predation. Orioles are probably regularly attacked by birds of prey, but reports of such events are only anecdotal. When feeling threatened, orioles usually fixate on the danger for a short period, in motionless posture, before they retreat to a higher perch in the canopy. When encountering unexpected noises or other potential threats while foraging on the ground, however, the Eurasian Golden Oriole immediately seeks cover. In attempts to avoid an attacking Eurasian Sparrowhawk (*Accipiter nisus*), one individual reportedly escaped into a woodpecker hole, and another hid under the edge of a roof. A further individual of this species hid in dark rock crevices to escape the attentions of an Eleonora's Falcon (*Falco eleonora*). Migrating Eurasian Golden Orioles

Fruits and invertebrates provide the vast majority of the nutritional needs of orioles, but at times other items may be consumed.

This **Eastern Black-headed Oriole** is visiting an aloe (Aloe). The berries of this plant are a frequent foodstuff for this species, but this individual is using its long bill to reach inside the aloe flower to sip the nectar. The Eastern Black-headed Oriole also feeds on aloe pollen and on both the nectar and pollen of coral (Erythrina) trees. When breeding, however, this oriole tends to provision its nestlings with insects and caterpillars; the size and species of the caterpillar increases as the chicks grow. The quest for caterpillars may induce the Eastern Black-headed Oriole to descend to low shrubs or even the ground, but normally this species prefers to forage in the canopy. While it usually feeds alone or in pairs, it may be attracted in small groups to fruiting trees, and immatures in particular frequently join mixed-species flocks.

[*Oriolus larvatus larvatus*, Pafuri, Kruger National Park, South Africa. Photo: Warwick Tarboton]

Aloes (Aloe) are important for **Eastern Black-headed Orioles**, providing a direct source of food and at the same time a foraging substrate. This species eats both the berries and the nectar of aloes, but these same food types also attract insects, providing the birds with a third potential food source on a single plant. The Eastern Black-headed Oriole mostly gleans its insect prey from the vegetation, but a swarm of winged termites (Isoptera), for example, may tempt it into some aerial flycatching. It readily feeds on insects as diverse as locusts (Orthoptera), beetles (Coleoptera) and honeybees (Apis).

[*Oriolus larvatus larvatus*, Kruger National Park, South Africa. Photo: Hanne & Jens Eriksen]

are frequently captured by Eleonora's Falcons in the Mediterranean region and by Sooty Falcons (*Falco concolor*) in Ethiopia. Other raptors recorded as preying on this oriole are the Booted Eagle (*Hieraaetus pennatus*), Red (*Milvus milvus*) and Black Kites (*Milvus migrans*), the Common Kestrel (*Falco tinnunculus*), the Red-footed (*Falco vespertinus*), Lanner (*Falco biarmicus*) and Peregrine Falcons (*Falco peregrinus*), the Northern Goshawk (*Accipiter gentilis*) and the Eurasian Buzzard (*Buteo buteo*). The Eurasian Eagle-owl (*Bubo bubo*), Northern Long-eared Owl (*Asio otus*), Ural Owl (*Strix uralensis*) and Tawny Owl (*Strix aluco*) have also been recorded as taking Eurasian Golden Orioles as prey. Peregrine Falcons and Japanese Sparrowhawks (*Accipiter gularis*) attack and sometimes kill Black-naped Orioles, and Black Sparrowhawks (*Accipiter melanoleucus*) and Peregrines have both taken Eastern Black-headed Orioles.

An intriguing anti-predator response is exhibited by adult Eurasian Golden Orioles, which, when threatened, adopt a stiff posture with beak turned upwards, similar to that of a bittern (*Botaurus*) when disturbed or alarmed. This behaviour is demonstrated also by fledglings when warned by their parents, and it is already evident even among nestlings; the latter, if a parent gives a warning call, press themselves flat into the bottom of the nest but keep the bill pointing upwards. Dodging all dangers, ringed Eurasian Golden Orioles reached a maximum age of eight years, with an average of 1.5 years for ringed nestlings and 3–4 years for individuals that had reached adulthood.

Orioles must drink, and they may do so in various ways. The Eurasian Golden Oriole may pump or suck water, as well as nectar, upwards into its downward-pointed beak, or it may use a sequence of alternately pumping and raising its beak, a "suck-and-tilt" process. Usually, this species drinks from tree hollows, takes dew or raindrops from branches or leaves, or flies closely above the surface of a waterbody and quickly dips its bill. In rare instances, it will also drink from rain puddles.

The Eurasian Golden Oriole bathes by diving down rather steeply from a waterside tree or bush, splashing briefly on to the surface of the water and immediately returning to the original perch or another one, a method recorded also for the Indian Golden Oriole. Alternatively, the former species will bathe in the manner of swallows (*Hirundinidae*) by gliding just above the water and briefly dipping its breast and belly. It will also bathe in the shallows along the water's edge or in wet foliage. During rainshowers,

several individuals have been observed to hang upside-down from a branch, with the wings held open. Bathing is usually followed by an extensive and vigorous grooming bout in order to rearrange and clean the feathers, a task for which orioles prefer high and covered perches. A group of Australasian Figbirds, for example, started rain-bathing high up in some fig trees (*Ficus*) by lowering the head and fanning the tail; the birds then slowly slid under the perching branch into an upside-down position, where they cupped the wings for 1–3 seconds, after which they returned to an upright position to shake, ruffle and groom the entire plumage. This performance was repeated several times. An Olive-backed Oriole rain-bathed in a similar upside-down position, but with its head thrown back, its wings fully opened and its tail fully fanned. Orioles may also sun-bathe, but the function of this behaviour is less clear, as it may be used for comfort, for thermoregulation or for the control of ectoparasites. Anting has not been recorded for any of the family.

Voice

As already discussed, a plausible explanation for the origin of the name "oriole" is that it is onomatopoeic (see Morphological Aspects). Although this derivation is associated with the Eurasian Golden Oriole, which does indeed utter a clear "o-ri-ole" call, the songs and calls of many other species in the genus *Oriolus* have the same sweet, liquid, fluting characteristics, making them immediately recognizable as emanating from an oriole. Similarly widespread among the *Oriolus* species, having been recorded from at least 17 species, is a harsh nasal call, variously described as growling, sneezing or screeching, or a cat-like "miaouw". Figbirds utter a series of simple tuneless whistles and short sharp yelps.

The complexity of oriole calls varies greatly among the species. Several species, instead of producing clear musical calls, will at times emit a prolonged jumble of syncopated sweet notes, as demonstrated by the Black-hooded Oriole. The Philippine Oriole delivers a series of rapidly repeated simple syllables for an extended period, and the Dark-throated Oriole accompanies such a vocalization with tail-flicking; in the case of the Black-naped Oriole, several individuals join together in producing this rapid series. Three of the species in the "African black-headed group", namely the Black-winged Oriole and the Eastern Black-headed

Orioles require to drink water. Hanging almost vertically downwards, this female **Indian Golden Oriole** has plunged the tip of its bill beneath the surface of the water, and is forcibly sucking upwards into her mouth. The Eurasian Golden Oriole (*Oriolus oriolus*) deploys an additional technique, putting its bill into water and then tilting its body back to allow the water to run into its mouth.

[*Oriolus kundoo*, India. Photo: Gertrud & Helmut Denzau]

Male orioles, such as this **Maroon Oriole**, play the lead role in courtship. The male performs a variety of aerial manoeuvres in front of the female, calling all the while. He then demonstrates his physical prowess by beating his wings, ruffling his mantle and crown feathers, and fanning his tail. Aerial chases may follow. Should the female be receptive, these may result in copulation, usually on a branch or on the nest itself. As the male hops around the female whistling, she calls back to him and places her tail to one side to facilitate mounting.

[*Oriolus traillii*,
Photo: Chien Te Wang]

and Western Black-headed Orioles, have very varied and extensive repertoires, and another in that group, the Sao Tome Oriole, also exhibits much variation. Three species in this group, the Mountain, Eastern Black-headed and Black-winged Orioles, may extend their calls into a duetting sequence between male and female. Similarly, the Eurasian Golden Oriole will perform a quiet antiphonal duet, and in New Guinea the Brown Oriole duets but the performance is poorly synchronized.

Western Black-headed, Eastern Black-headed, Brown and Olive-backed Orioles are excellent vocal mimics of several other species. In the case of the Brown Oriole, this includes its visual mimic, the Helmeted Friarbird, the call of which the oriole also uses in the duetting sequence. Likewise, the Black-eared Oriole is said to be a vocal mimic of the Black-faced Friarbird, which it closely resembles in appearance (see Morphological Aspects).

The vocalizations of orioles have provided some corroborative support in taxonomic diagnoses, most recently as one of the characters separating the Eurasian Golden and Indian Golden Orioles at the species level. In other cases, some clear vocal differences among taxa have not yet persuaded taxonomists that they provide sufficient evidence for the "splitting" of species. As an example, the call of the "White-lored Oriole" is different from that of the Philippine Oriole, within which it is currently placed as the subspecies *albiloris*, and the extensive racial differences within the Black-naped Oriole complex remain largely unstudied.

Food and Feeding

Orioles are omnivorous and almost exclusively arboreal, foraging mainly high in trees. They feed chiefly on berries, fruits and invertebrates, with some other foods taken opportunistically. The latter include, for example, nectar, pollen, flowers, flowering shoots, leaf buds, seeds of, among others, barley, oats and grasses, and vertebrates such as lizards and small mammals, as well as bird eggs and nestlings. While the three *Sphecotheres* figbirds feed mostly on fruits, the *Oriolus* species take much more animal food, although the proportion of fruits to invertebrates in the diet varies widely, depending on species, sex, age, habitat and season. As an example, the Eurasian Golden Oriole apparently consumes more fruit during migration and winter than it does during the breeding period, and it feeds its growing young with progressively more fruit, if this is available.

Foraging orioles keep mainly to the canopy and middle storey, where they detect food items mostly by sight but sometimes by sound, and then glean or snatch these from branches and foliage. While searching for food, orioles move through the vegetation in short flights and hops or by climbing, but they may also use other body postures, including hanging upside-down, in order to reach food. Sometimes they will catch insects, such as winged termites (Isoptera), in mid-air, and they are also able to hover in a kestrel-like manner to glean items from the undersides of leaves or to locate prey from close above. Orioles sometimes forage in lower levels of vegetation if a good food source is available, as along forest edges or in clearings, treefall gaps or fruiting shrubs. Rarely, however, are they seen to forage on the ground, a substrate which they usually exploit only when pursuing large invertebrates, picking up fallen fruit or foraging in mostly treeless habitats. In pursuit of terrestrial prey they often hover before pouncing to the ground, where they hop or briefly fly but rarely walk.

Orioles consume a wide variety of invertebrates, including earthworms (Oligochaeta), leeches (Hirudinea) and snails (Gastropoda), and arthropods such as spiders (Araneae) and a multitude of insect taxa. Among the last, damselflies and dragonflies (Odonata), crickets, katydids, grasshoppers and locusts (Orthoptera), preying mantises (Mantodea), termites, mealy bugs (Pseudococcidae), shield bugs (Acanthosomatidae), jewel bugs (Scutelleridae), stink bugs (Pentatomidae), cicadas (Cicadidae), weevils and other beetles (Coleoptera), snakeflies (Raphidioptera), mantid flies (Mantispidae), caddis flies (Trichoptera), gadflies (Tabanidae), hoverflies (Syrphidae), crane flies (Tipulidae), moths and butterflies (Lepidoptera), and such Hymenoptera as wood wasps (Siricidae), diprionid sawflies (Symphyta), ichneumon wasps (Ichneumonoidea), ants (Formicidae), hornets and wasps (Vespidae), and bumblebees and bees (Apoidea) have all been recorded as prey. Besides consuming adult invertebrates, orioles eat eggs, pupae and larvae, an oriole's apparently favourite meal being caterpillars, both hairless and hairy. It is worth remembering that hairy caterpillars are a potential food item that is avoided by most other bird species.

In addition to animal food items, orioles take an equally wide variety of fruits and berries, including those of alien species. The figbirds are, as the vernacular name implies, very fond of figs, but no fewer than 16 oriole species have been observed also to take figs, and it is likely that most other species take these fruits but have not so far been recorded as doing so. Orioles do not shy

Once a pair-bond has been established, orioles choose a nest-site within their foraging territory. The partners then set about constructing their nest. This male **African Golden Oriole** has collected strong, supple material to form the core structure of the nest. Grass, rootlets, stems, tendrils, and leaves are all suitable for this purpose. Spider-web silk may be used to bind the components together, thereby providing rigidity. To provide a warm, soft interior, the birds collect woolly plant down or feathers or animal hair.

[*Oriolus auratus*.

away from commercial orchards, either, and they are therefore sometimes considered agricultural pests. As a consequence they are persecuted at times (see Status and Conservation), especially during migration periods, when large numbers may assemble in the same orchard.

Less easily digestible food items, such as hairy caterpillars or hard-shelled insects, and fruits are typically prepared for up to five minutes before being consumed. This preparation involves the pressing, mandibulating, shaking or ripping of the item, or the vigorous brushing and pounding of it against a hard surface,

usually the perch, but the bird does not use the feet to hold the prey while it is being prepared in this way. Such manipulation makes caterpillars, for example, more digestible by removing their hairs and pulping the body, and it is often employed by the adults before feeding such items to the young. Likewise, the parents sometimes squeeze fruits so that the juice enters the mouth of the young chicks. Hard indigestible food items, such as chitinous body parts of insects, are later regurgitated.

Breeding

Breeding seasons are determined by seasonal climatic patterns, with some tropical species breeding throughout the year. While knowledge of the breeding behaviour of many oriole species is only rudimentary or non-existent, what we do know reveals an astonishing uniformity within the family, as the details for many of the species are more or less identical. More is known about the breeding behaviour of the Eurasian Golden Oriole than about that of any other oriolid but, apart from the figbirds, the breeding behaviour of the other members of the family appears to be very similar. So far as is known, all orioles are socially monogamous. Birds in the genus *Oriolus* evidently defend exclusive territories, while the *Sphecotheres* figbirds breed in loose colonies.

Courtship among orioles consists mainly of calls and aerial chases, the male flying, diving, hovering, wing-beating and tail-fanning in view of the female. Aerial chases are sometimes followed by copulation. The male whistles and hops around the female, and she entices her partner with screeching calls and by fanning her tail to one side to allow the male to mount. This he does up to four times, after which he may resume hopping or chasing. Copulation usually takes place on branches or on the nest. It is not known whether females elicit secretive extra-pair copulations. More rarely, several males may engage in lek-like courtship displays directed at a single female, features of which include aerial chases involving two males or one male and a female, and simultaneous or alternate calling.

A very elaborate courtship display by a male Eastern Black-headed Oriole was observed in Kenya. Having flown down to the branch of a small tree, the male fanned his tail, partly opened his wings, depressed his head and, in this position, slowly revolved on the branch. He then bent down, suddenly brought his fanned tail over his back, and lowered his wings and spread them

The nest of this **Eastern Black-headed Oriole** is typical of the genus *Oriolus*. It is cup-shaped, and in this instance quite deep, although others may be shallower. The cup is open, meaning that the incubating female has to provide her eggs and subsequent chicks with protection from the elements. The location of this nest also appears typical: suspended like a hammock in a slim, horizontal fork, deep inside a leafy canopy. The female takes sole responsibility for building the nest, the male proclaiming their territory by vocalizing nearby.

[*Oriolus larvatus larvatus*,
Stone Hills Game
Sanctuary, Zimbabwe.

fully. Throughout the performance, the oriole called continuously with a mixture of imitations of starling (*Sturnidae*), sunbird (*Nectariniidae*) and robin-chat (*Cossypha*) calls interspersed with the liquid notes which the male of this species ordinarily utters. After a short silence, he displayed again, but this time with the head raised and the neck outstretched, the fanned tail held high, and the wings partially opened and held low on the branch as he bobbed up and down.

After pair formation, the partners collaborate in looking for potential nest-sites, which may be anywhere within the pair's

feeding territory. Several Asian and Australasian species will deliberately select a nest-site near the nest of more aggressive species, such as drongos, butcherbirds (*Cracticidae*) or friarbirds, which may afford some protection against nest predators. For example, both Slender-billed and Black-hooded Orioles will nest near Black Drongos (*Dicrurus macrocercus*), the Brown Oriole may nest near Hooded Butcherbirds (*Cracticus crassicus*) or Helmeted Friarbirds, and the Olive-backed Oriole may seek out nesting colonies of Australasian Figbirds, while the Australasian Figbird, in turn, may nest in association with Helmeted Friarbirds or Spangled Drongos (*Dicrurus bracteatus*). Likewise, the Eurasian Golden Oriole occasionally builds its nest near those of, for example, Fieldfares (*Turdus pilaris*), Great Grey Shrikes (*Lanius excubitor*) or Lesser Grey Shrikes (*Lanius minor*).

The typical oriole nest is a shallow to deep, open cup densely woven from various plant materials, decorated with moss and lichens, and suspended hammock-like in a thin, horizontal fork on a lateral branch high inside a well-foliaged tree canopy. If a suitable support is not available, the oriole may create one by weaving together several thinner branches. The nest is very tough and capable of withstanding severe storms. It is built mostly or entirely by the female, the male sometimes helping by collecting some nest material; the building work is completed within 1–2 weeks, exceptionally longer. Figbird nests, by comparison, are not woven and are simpler and flimsier structures, loosely put together from twigs and with no inner lining. For orioles, nest-building requires pliable material for fixing the main structure, soft material for lining, and other material suitable for camouflage. Materials utilized for nest-building are probably chosen opportunistically, as is illustrated by the use of animal items such as hair, feathers and even snakeskin, and man-made materials such as paper, string, plastics and textiles, once even stolen from a scarecrow. Around the beginning of the twentieth century, one lucky finder retrieved a 1000 franc banknote from a nest. During the First World War, a nest of the Eurasian Golden Oriole was found to have been made entirely of surgical dressings pilfered from a nearby dressing-station; after the Second World War, nests made almost entirely out of aluminium strips dropped by bombers to deflect the enemy's radar were found. Most nesting material, however, is plant-based and from a variety of sources, sometimes stolen from the nests of conspecifics or other species.

In a few orioles, the sexes share the parental responsibilities of nest-building, incubation, brooding and provisioning. The more frequent scenario, however, is that the female oriole does most of the work. This is the case with the **Eastern Black-headed Oriole**, where the female alone incubates the eggs and broods the nestlings. Incubation lasts 14–16 days, a relatively short duration for an oriole, some other species incubating for up to three weeks. During this vulnerable period, the female must take care not to attract the attention of potential predators. She thus sits very still while on the nest, scanning the surroundings for any sign of danger.

[*Oriolus larvatus larvatus*, Nylsvley Nature Reserve, Modimolle, South Africa. Photo: Warwick Tarboton]

The breeding characteristics of the **Green Oriole** of Australasia and east Indonesia are fairly typical of the genus *Oriolus*. The nest is a deep cup, woven from coarse and pliable material such as tendrils, twigs and grasses, and lined with softer material such as wool. The female does most of the incubating and brooding, the male helping occasionally. Both parents feed the young, but regurgitate food rather than providing whole items. The male proclaims territory ownership by singing all year, but the breeding season is usually confined to the months between August and January.

[*Oriolus flavocinctus kingi*, Ingham, N Queensland, Australia. Photo: Clifford & Dawn Frith]

Clutch size varies from one to six in orioles, depending on species and individual circumstance. The **Olive-backed Oriole** falls around the median of this range, normally laying two or three eggs. Incubation lasts 16–18 days. At hatching, oriole nestlings are naked and immobile, and have closed eyes; they are thus utterly dependent on their parents. Both Olive-backed Oriole parents feed the chicks, primarily with regurgitated food. The chicks stay in the nest until they are able to fly, leaving at 15–17 days old. They continue to be fed by both parents or by the male alone if the female is occupied in constructing a new nest to house a second brood. Once independent, they leave their natal territory to settle elsewhere. Interestingly, the Olive-backed Oriole often nests in or near colonies of the Australasian Figbird (*Sphecotheres vieilloti*). Australian populations of the Olive-backed Oriole resemble this figbird species and it is thought that this may be a case of mimicry.

[*Oriolus sagittatus sagittatus*,

Brisbane, Queensland, Australia.

Photo: Raoul Slater]

While building the nest, the female may alight in a neighbouring tree, before secretively hopping to the nesting site itself a little way away. She often uses saliva both to soften vegetable fibres and to glue the first few strips, 20–40 cm in length, to the branches, and frequently uses cobwebs for binding. After tightly wrapping the preliminary strips around the holding branches to produce a basic hammock-like structure, the female then intricately weaves further vegetable fibres into the basic structure, using her beak to pull fibres from the outside to the inside of the nest and from the inside to the outside. Once the nest's structure has reached a certain degree of sturdiness, its shape is constantly improved by the female turning and pressing against the inside.

Oriole clutches vary from one egg to six, but the average is about two to three eggs, usually laid at intervals of 1–2 days. The eggs measure approximately 2×3 cm and weigh 5–10 g. They are sometimes white or pinkish-white but mostly some sort of creamy colour, with reddish, brownish, purplish, greyish and blackish spots and streaks, these markings usually concentrated at the obtuse end. The eggs of figbirds, however, are duller, having a greyish-green to olive-brown ground colour.

Although, with some members of the family, it appears that both sexes build the nest, incubate the eggs, and brood and feed the nestlings, this is the exception. More usually, it is exclusively or almost exclusively the female that incubates, for a period of 2–3 weeks, and that broods the nestlings, again for 2–3 weeks. While incubating, the female of the Eurasian Golden Oriole leaves the nest to feed herself only for brief periods of about ten minutes, and rarely up to 38 minutes, but she leaves for longer foraging trips after the eggs have hatched. Meanwhile, the male may feed her and he may also incubate or brood for short periods.

The nestlings of orioles and figbirds are altricial and nidicolous. Both sexes feed them, in the early stages mostly with

small invertebrates, especially caterpillars, but later also with larger invertebrates and more and more berries and fruits, if these are available. The proportion of regurgitated food, as opposed to fresh, unregurgitated food, decreases as the young grow. In the Eurasian Golden Oriole, both male and female feed the chicks, at a rate of around 9–15 times per hour, but sometimes up to 24 times per hour, and with up to 211 feeds in a day. Nestlings begin to beg clamorously, with the open bill turned upward, as soon as they feel the vibrations and hear the sounds of an arriving parent; after opening their eyes at about 6–8 days of age, they also detect the parents' presence visually. The parents at first swallow the chicks' faecal sacs but they carry them away from the nest once the young are about 8–10 days old, at which time the chicks' digestion has become so efficient that their faecal sacs no longer contain any appreciable residual nutrients. Brood-feeding decreases or ceases altogether during the hot midday hours or during periods of bad weather, when nestlings will cuddle together for warmth and, in strong winds, use their claws to cling tightly to the bottom of the nest. During heavy rainfall, the female protects the nestlings by sitting on top of them; at times of intense heat, she may shade them while they pant to lose heat and, in such conditions, the chicks often spread out to such an extent that their heads may protrude over the edge of the nest.

Adverse weather decreases nesting success by depleting food resources, particularly invertebrates, or by directly killing nestlings or destroying nests. After such events, depending on circumstances, pairs may quickly make a new breeding attempt, or they may forgo breeding for the year in question. Exceptionally bad weather, such as hailstorms, can even kill adults.

Orioles use several strategies to defend the nest against predators and conspecifics. As has been seen, one is to build the nest close to the nests of combative species, which may themselves

chase off potential nest predators. If danger approaches, however, the female crouches low in the nest, or slinks away quietly to hide nearby, returning only once the danger has passed. Potential nest predators such as cats, martens (*Martes*), mice (*Muridae*), squirrels (*Sciuridae*), shrikes, starlings, and such corvids as ravens, crows, magpies and jays, as well as owls (*Strigidae*) and birds of prey, are actively chased away, the oriole sometimes defecating on them, and neighbouring pairs occasionally joining in. Orioles rarely resort to direct physical attack, but in a few instances they have been recorded as actually killing an intruding predator by using the bill. Known nest parasites of orioles, such as the Common Koel (*Eudynamis scolopaceus*) and other cuckoos

(Cuculidae), are also chased away. Once the young start begging for food, a warning call by one of the parents silences them immediately and causes them to crouch motionless in the nest.

Telemetric studies of the Eurasian Golden Oriole in northern Germany showed that, during the breeding season, the adults foraged for 45% of the time within 200 m of the nest and for 80% of the time within 700 m of the nest, but they would travel 1–3 km for especially abundant food sources, such as plants infested with caterpillars. Their foraging ranges increased significantly after the hatching of the eggs. Sometimes, up to three immature or adult orioles, presumably previous offspring of the nesting pair, helped in the feeding of the young, especially in habitats with poor food availability. A similar phenomenon has been recorded for the Australasian Figbird, the nestlings of which are occasionally brooded and fed by extra males and females.

Nestlings of the Eurasian Golden Oriole begin to preen and to exercise their wings when they are about 10–12 days old, which is the time when most down feathers start to be replaced with adult feathers. A few days later, some leave the nest and perch in the immediate surroundings, sometimes on the ground. They start to fly when 16–20 days old, after which the young stay with the parents in family groups for a few weeks, or perhaps even months, feeding by the parents eventually ceasing altogether. Orioles probably breed for the first time at the age of 2–3 years, as demonstrated for the Eurasian Golden Oriole.

Studies of Eurasian Golden Orioles have revealed that this species can exhibit site-fidelity over several years. In a few cases, ringing has confirmed that both male and female returned to the same territory year after year. Usually the pair chooses a new nesting site but will occasionally occupy the same nesting tree, or indeed the same branch. Orioles may even reuse materials from the previous year's nest or, rarely, will use the old nest, merely repairing it with some new material. Both the Eastern Black-headed Oriole and the Eurasian Golden Oriole have on rare occasions been recorded as using the same nest a year later.

Movements

Among the Oriolidae, only two species are long-distance migrants, the entire populations of which move seasonally. The Eurasian Golden Oriole migrates between breeding grounds in the Palearctic Region and non-breeding areas in the Afrotropics,

While incubating, the female **Eastern Black-headed Oriole** is fed by the male. It is essential that the male delivers sufficient food for the female to maintain her metabolic rate as this, in turn, generates the heat needed to maintain the eggs at the correct temperature. In this species, clutch size is usually 2–3. Of these, however, an average of just 1.1 chicks lives long enough to fledge. Once the eggs have hatched, the female Eastern Black-headed Oriole takes primary responsibility for brooding the chicks. The male, however, shares some of the brooding duties, and both sexes provide food.

[*Oriolus larvatus larvatus*, Stone Hills Game Sanctuary, Zimbabwe. Photo: J. R. Peek]

When oriole chicks are recently hatched, their parents feed them by regurgitating food. As the chicks grow, however, they become increasingly able to digest solid food. Accordingly, their parents increase the frequency of delivery of small, protein-rich invertebrates, as illustrated by this **Eastern Black-headed Oriole**. It does not take long for the chicks to learn that sudden vibrations and sounds at the nest signify the arrival of a parent with another meal, and they beg vociferously with bill agape and pointing upwards towards the adult bird.

[*Oriolus larvatus larvatus*, Stone Hills Game Sanctuary, Zimbabwe. Photo: J. R. Peek]

A total of two nestlings constitutes a rather small brood for the **Eurasian Golden Oriole**, as normal clutch size is 3–5 eggs. After being incubated by the female for 13–20 days, the eggs hatch within two or three days of each other. The female takes charge of brooding, but both sexes forage. Studies of breeding Eurasian Golden Orioles reveal that parents tend to feed their young 9–15 times per hour, which places a considerable burden on them. While almost half the time spent searching for food is within 200 m of the nest, adults are prepared to travel up to 3 km to reach particularly abundant food sources.

[*Oriolus oriolus*, Spain.

Photo: José Luis Rodríguez]

and the Silver Oriole moves between southern China, where it breeds, and Thailand and Cambodia, where it spends the non-breeding season. In eight other species, only parts of the population are migratory while others are sedentary; these are the Olive-backed, Indian Golden, African Golden, Black-naped, Slender-billed, Eastern Black-headed, Black-hooded and Maroon Orioles. The remaining 20 species in the family are largely sedentary, but may move short distances in response to food fluctuations, or the young may roam about, or “float”, while seeking to establish new territories. Whether individuals fly only a few kilometres or thousands of kilometres, the overriding reason for movements is the search for adequate food supplies, largely in the form of fruits and invertebrates (see Food and Feeding). It is usually, therefore, that part of the population living in areas where the winters are harshest that migrates, while sedentary populations are found in more stable climates.

Most is known about the migration of the Eurasian Golden Oriole, but the movement-related habits of this species are probably similar to those of other orioles which migrate. Migration is usually preceded by heavy bouts of feeding to promote the accumulation of fat reserves, a phenomenon observed also for the African Golden Oriole. Spring migration is faster, more direct and more diurnal than is autumn migration. This is because the males are competing to establish breeding territories as early as possible, and because the females, although usually arriving up to ten days later than the males, need to reach the breeding grounds in time to begin nesting in the optimal period. No such pressing needs push the birds during autumn migration, when the Eurasian Golden Oriole migrates at a more leisurely pace and reportedly mostly at night, probably in order to avoid predators (see General Habits). Adverse weather may pose another threat, as it can delay the spring migration of both the Eurasian Golden Oriole and the Black-naped Oriole by several weeks.

Eurasian Golden Orioles usually migrate alone or in small flocks of up to 30 individuals, although hundreds may gather around fruit resources, especially in gardens and orchards. In exceptional circumstances, even larger concentrations are recorded; for example, thousands were seen together south-west of Alexandria, in north Egypt, on 27th April 1982. Flight altitude can vary. Recorded heights during diurnal passage southwards vary between 5 m and 100 m while over land, many orioles then crossing the Mediterranean Sea at altitudes of 200–300 m but ascending to 1500–2000 m on reaching the Sahara. Within the

Afrotropics, with no need for breeding, the only consideration for Eurasian Golden Orioles becomes that of staying alive. This requires mainly that they follow the wet season as it moves southwards across the continent, since rainfall triggers the growth of green vegetation and a subsequent bonanza of caterpillars and other large invertebrates.

Relationship with Man

Several oriolids, among them the Eurasian Golden Oriole, the Eastern Black-headed Oriole and the Australasian Figbird, occa-

As might be expected for a predominantly frugivorous genus, the **Australasian Figbird** has few qualms about feeding its offspring with fruit and berries as soon as the nestlings' digestive systems are up to it. This female has returned to the nest with a berry that it will feed to one or more chicks. The three youngsters shown in this photograph are typical for the Australasian Figbird, the female only rarely laying either two or four eggs. The species breeds from October to February in the south of its range, extending by a month either side further north. Pairs may raise one or two broods per year. While no information exists on the breeding behaviour of the other two figbirds (*Sphecotheres*), a similar pattern can be expected.

[*Sphecotheres vieilloti*, Vieillot,

Goomboorian, Gympie, SE Queensland, Australia. Photo: Cyril Webster]

Upon hatching, figbird nestlings rapidly demand food from their parents. They are unable to deal with solid food, however, so meals over the first few days of their life comprise food regurgitated by the adults. In these photos, a female (above) and male (below) **Australasian Figbird** are in the middle of the regurgitation process. Over time, the nestlings will move onto a diet of intact invertebrates, fruit and berries. The adults seen here are probably, but not necessarily, the chicks' parents: Australian Figbirds are unusual among the Oriolidae in that nestlings are occasionally brooded or fed by adult helpers in addition to their parents. Such occasional co-operation is particularly interesting in the context of the Australasian Figbird breeding in loose colonies, which are often located close to the nests of Helmeted Friarbirds (*Philemon buceroides*) or Spangled Drongos (*Dicrurus bracteatus*). Figbird nests are rather flimsier structures than the neat cup of orioles, and comprise simple saucer-shaped arrangements of tendrils with no attempt at a softer, warmer inner layer. The nest is supported against a fork towards the tip of a roughly horizontal branch.

[*Sphecotheres vieilloti* vieilloti.]

Once the eggs of an oriole pair have hatched, the bulk of the breeding adults' energies are devoted towards bringing food to the nest. With so much food arriving, the removal of excreta is essential in order to keep the nest clean and to reduce detectability. This male **Eurasian Golden Oriole** is in the process of collecting a faecal sac. For the first week or so, the adults swallow their nestlings' faecal sacs, but thereafter they carry the white sacs a safe distance from the nest, where they can be disposed of without drawing attention to the vulnerable nestlings.

sionally cause damage to fruit crops in gardens and orchards, and have consequently been persecuted. It is very likely that other oriole species have met the same fate.

Orioles have been exploited by humans for food, sport hunting, the cagebird trade, taxidermy and medicine and for their eggs (see Status and Conservation). In the Altai Mountains of Central Asia, orioles were used by shamans in their religious rituals. Farther west, in the Chuvashskaya Republic of European Russia, the cooked feathers of the Eurasian Golden Oriole were believed to cure malaria and yellow fever, and in Hungary the nests of this species were burnt to produce a cure for mastitis in cows. African Golden Orioles were occasionally sold in markets in Nigeria, probably for traditional medicinal purposes, and the flesh of the Black-naped Oriole has been eaten by pregnant women in South-east Asia supposedly to make their babies more beautiful.

The Eurasian Golden Oriole is considered a harbinger of summer in Europe, and has been called the "Whitsun-bird" because of its late arrival in central Europe, the religious festival of Whitsun, or Pentecost, coming seven weeks after Easter. This species has been named the "beer-bird", because Whitsuntide used to be marked by a festival with a lot of merriment and ale-drinking. It has further been called "rain-bird" or "rain-cat", as it is sometimes the only bird to sing in the humid weather conditions that precede a thunderstorm. K. D. Feige, in his German-language monograph of the Eurasian Golden Oriole, lists more than one hundred colloquial names for this species. For example, this species' dietary preferences are reflected in such colloquial names as "cherry-thief", "fig-eater" and "grape-thrush", just as the name "mango-bird" for both the Indian Golden Oriole and the Black-hooded Oriole indicates one of the favourite feeding trees of these members of the family. The Indian Golden Oriole has also been endowed with the native name of *Peeluk*, meaning "The Yellow One", on account of its brilliant plumage, and the Eurasian Golden Oriole likewise has colloquial names such as "yellow-bird", "gold-bird", "gold-thrush" and "olive-thrush" in Arabic, English, German, Icelandic, Luxembourgish, Norwegian and Swedish.

The mournful whistled song of the Eurasian Golden Oriole evokes sad feelings in some people, apparently especially so among Russians. This is evidenced by the poem "I hear the always-sad voice of the oriole" by the Russian writer Anna Akhmatova which salutes the passing of the summer, as well as by the documentary movie "Somewhere laments an oriole...", by the Russian film-maker Edmond Keosayan, which tells the story of a Russian girl who, during the Second World War, was brought from Russia to Belgium, where she became an active Resistance fighter. Another book referring specifically to orioles is R. Trevelyan's *The Golden Oriole: Childhood, Family and Friends in India*, in which the author describes his journey across India as he revisits the places of his childhood and evokes the spirit of the British experience in colonial India.

Finally, one of Germany's best-loved comedians, Vicco von Bülow, whose last name is itself an onomatopoeic spelling of the oriole's song, adopted the French name of the oriole, *Loriot*, as his stage-name. The Eurasian Golden Oriole is quite a popular bird in Germany, with three excellent German monographs published in the last two decades: in addition to the one by Feige, there are those contributed by E. Bezzel and R. Wassmann. Bezzel's monograph celebrates the oriole being awarded the title of "Bird of the Year" in 1990, an honour bestowed annually on a particular bird species by the German BirdLife partner in order to raise conservation awareness among the general public.

Status and Conservation

Of the 30 species of Oriolidae currently recognized, three are globally threatened and a further three are listed as Near-threatened. This total of six species amounts to 20% of the family, the same as the global average for all avian families. Top of the list is the Critically Endangered Isabela Oriole of the north Philippines, rediscovered in 1993 after a 32-year absence of records, followed by the Sao Tome Oriole and, in south China, the Silver Oriole,

Adult orioles provide their offspring with a varied diet. Taken at the same **Olive-backed Oriole** nest, the first image shows the parent bringing back a bill full of black berries, whereas in the second it delivers a stick-insect (*Phasmida*). The insect is rather large, and the adult will probably have to break it into pieces before passing it on to the chicks. Judging from the limited fine streaking on the crown and the lack of any cinnamon edging to the remiges, the adult seen in both of these photographs appears to be the male.

[*Oriolus sagittatus sagittatus*, Goomboorian, Gympie, SE Queensland, Australia. Photos: Cyril Webster]

The two nestlings of this male **Black-naped Oriole** have lost their down and have developed yellow-olive adult feathers, which suggests that they are probably only a day or two from fledging. Both parents will continue to care for their offspring within the family's territory until the young become independent.

the current status of each of which is considered to be Vulnerable. The Dark-throated Oriole, the Black Oriole and the Wetar Figbird (*Sphecotheres hypoleucus*) are not yet thought to be at immediate risk and are placed in the conservation category of Near-threatened.

The Isabela Oriole is apparently dependent on the lowland rainforests, and especially thick bamboo forest, on the Philippine island of Luzon, where it has had to contend with a 75% reduction of its habitat over the last century. Although this species has been recorded also in second growth and forest edges, primary forest habitat is probably of crucial importance for its continued survival. Likewise, the Sao Tome Oriole and the Silver Oriole appear to be dependent mainly on primary forest, utilizing mature secondary forest to a far lesser extent. Of the Near-threatened species, the Dark-throated Oriole and the Wetar Figbird use both primary and secondary forests, while the Black Oriole seems to be restricted to primary forest.

All six of these species have relatively small global ranges, predisposing them to extinction, but the ultimate causes of their precarious status are anthropogenic, principally habitat loss, degradation and fragmentation brought about by logging, agricultural expansion and, to a much lesser degree, other forms of human encroachment such as road-building, mining and uncontrolled fires. Pesticide use is also implicated in the decline of the Sao Tome Oriole. In reality, it is not really known how dependent many of the 30 oriole species are on primary, undisturbed forest for long-term survival or whether they could also survive in patches of secondary forest. The protection of large tracts of forest must, therefore, be considered essential in view of the current limited knowledge of these species' ecology. The conservation of the Silver Oriole is further complicated by the fact that this oriole migrates between breeding grounds in China and non-breeding areas in Thailand and Cambodia, thereby necessitating conservation strategies for both regions.

Encouragingly, all globally threatened and Near-threatened members of the family except the Wetar Figbird occur in one or more protected reserves, with further areas in the process of becoming protected. Nevertheless, it remains highly questionable whether these limited forest patches will suffice to ensure the long-term survival of each species, in particular because some of these reserves are poorly managed and inadequately protected. All except one of the six oriolids that are threatened or poten-

tially threatened have been observed in degraded forest habitats, which may enable them to survive in a patchwork of primary and secondary forest remnants. It is not known, however, whether they can successfully breed in degraded or secondary habitats, which may therefore act as population "sinks", such that these species still depend on primary habitats for survival. The Black Oriole, the only threatened or potentially threatened species that has so far been recorded only from primary forest habitats, may also make use of secondary habitats but has not yet been observed in them.

The **Philippine Oriole** is one of a number of oriolids that are poorly known. It appears to be fairly common over much of its sizeable range, occupying much of the Philippines. However, as forest destruction and degradation in the Philippines have been so intensive, it seems likely that the numbers of this species will have declined somewhat, even allowing for the fact that this species is often found in secondary habitats. Further research is required on this species.

Several oriolids may soon be candidates for Near-threatened status, as they combine a medium-sized range, extending across 20,000–50,000 km², with continuing loss, degradation and fragmentation of forest. These are the Olive-brown Oriole, Black-eared Oriole, Grey-collared Oriole, Dusky-brown Oriole and Green-headed Oriole and the Timor Figbird (*Sphecotheres viridis*). These species should therefore be monitored, as they face similar ongoing threats to those afflicting the already threatened species, such as logging and agricultural expansion, with potential future threats that include oil-drilling activities and hydro-electricity schemes. Even widespread and common species are subject to some threats. For example, the Green Oriole and

the Australasian Figbird suffer from the continuing disappearance of rainforest patches with fruit resources, while the African Golden Oriole and the African Black-headed Oriole are partially dependent on miombo (*Brachystegia*) woodlands, which are vanishing fast. As a consequence, some maps depicting the ranges of oriolids may present an overoptimistic picture, and the true current range may be much more constricted than indicated. For example, it is well known that the Slender-billed Oriole is almost extinct in some areas of its Chinese range owing to habitat destruction, hunting, and trapping for the cagebird trade and taxidermy.

While its conservation status does not even approach that of globally threatened, the fate of the Eurasian Golden Oriole illustrates a number of other conservation issues. First, there has been a conspicuous northward expansion of its range, breeding populations having established themselves in Denmark, Sweden, Norway and the United Kingdom during the last two centuries. This expansion was probably caused by habitat change, such as the creation of poplar (*Populus*) plantations in East Anglia, in England, but perhaps also by gradual temperature increases. Recently, however, this oriole has experienced some regional population declines in western Europe the causes of which are much harder to pin down. In England, the recent decline has been due at least partially to the felling of the favoured poplar plantations, but other causes may be increased pesticide use, removal of trees and hedges and the disappearance of riparian forests in breeding areas, as well as losses during migration and in the non-breeding quarters due to hunting and to habitat loss and degradation. It is common knowledge that thousands of orioles are killed annually by hunters when they migrate through the Mediterranean region and along the Nile Valley, or at stopovers at Saharan oases. Sometimes this persecution is carried out in order to protect commercial fruit crops such as ripening dates and mulberries (*Morus*), but in most cases the birds are hunted for food or merely for "sport". Furthermore, some of the Eurasian Golden Oriole's favoured winter habitats, such as miombo woodlands, are vanishing fast in parts of the species' non-breeding range.

Whereas the Eurasian Golden Oriole is hunted heavily during certain stages of its migration, the Black-and-crimson, Black-naped, Dark-throated and Slender-billed Orioles, and probably other oriole species, are trapped for the purposes of taxidermy and the cagebird trade in China and other eastern Asian countries. Nets or bird-lime twigs are often used, or the birds are taken directly from the nest. The Black-naped and Slender-billed Orioles are now markedly rare in many areas of their

A rather drab-plumaged oriolid, the **Olive-brown Oriole** is a restricted-range species confined to the Timor and Wetar Endemic Bird Area in the eastern Lesser Sundas. At present, it is not considered to be globally threatened and was found to be common during recent surveys on Atauro. On Timor and Wetar, however, it is generally uncommon and thinly distributed. Given the rate of deforestation on these islands, and the existence of only a very few small protected areas, it would seem worthwhile monitoring the status of this species.

[*Oriolus melanotus melanotis*,
W Timor, Lesser Sundas.
Photo: Morten Strange]

The **Black-eared Oriole** (left) occurs on Buru and in the Tanimbar Islands, whereas further to the north the **Dusky-brown Oriole** (right) occurs only on Halmahera. While neither species is currently of global conservation concern, the logging concessions on Tanimbar and Halmahera, together with extensive deforestation on Buru, suggest that it would be wise to establish additional protected areas on these islands for these species and others.

The Dark-throated Oriole is fairly common in its relatively large range in South-east Asia, the Greater Sundas and the western Philippines. Moreover, it occurs in several widely spaced protected areas and tolerates both secondary growth and submontane elevations. Nevertheless, destruction of lowland forests in this region has been rampant, prompting dismal predictions of almost all the primary forest having disappeared by 2010. This attractive oriole is also sold in the cagebird trade. This combination of pressures has warranted the species' listing as Near-threatened.

Asian ranges as a result of overexploitation by humans, and no doubt the same applies to several other oriole species. Although some oriolid eggs may still be taken for food by local inhabitants, others are taken by egg-collectors, who are still active in, for example, England.

Some other human activities have unexpected consequences for oriole populations. While rising global temperatures may cause migrating orioles to arrive earlier at their breeding grounds and to leave later, the "Chernobyl disaster", in Ukraine, where a nuclear reactor exploded in 1986, led to an increase in Eurasian Golden Oriole populations as the birds began to breed in abandoned and overgrowing villages. Similarly, the Sao Tome Oriole

initially benefited from Portuguese decolonization, as many plantations reverted to secondary growth after 1975. So far as is known, no serious attempt has been made at introducing any oriole species into another part of the world.

In conclusion, while we certainly know factors that are detrimental to oriole populations, it is very difficult indeed to determine which factor is the most important for any given species. Considering all members of the family together, however, it seems that habitat loss, degradation and fragmentation are by far the most serious causes of population declines. The protection of large and undisturbed tracts of habitat has to be considered essential for the long-term survival of most of the Oriolidae.

Three species of oriole are globally threatened, one being the **Sao Tome Oriole**, which is rated Vulnerable. It is a restricted-range species endemic to São Tomé, with a total range of merely 480 km². While locally common in primary forest, historical clearance of forest for coffee and cocoa plantations means that suitable intact habitat has effectively retreated to higher elevations. Widespread pesticide use up to 1975 is thought to have caused a dramatic reduction in oriole numbers, and today possibly fewer than 1000 birds remain.

PLATE 54

inches 5
cm 13

Genus *SPHECOTHERES* Vieillot, 1816

1. Timor Figbird

Sphecotheres viridis

French: Spéciothère figuier **German:** Timorfeigenpirol **Spanish:** Oropéndola de Timor
Other common names: Green Figbird

Taxonomy. *Sphecothera* [sic] *viridis* Vieillot, 1816, “Austral-Asia” = Kopang, Timor. Original description of genus included two different spellings, “*Sphecotheres*” and “*Sphecothera*”; former selected by first reviser as the valid name for this genus. Has sometimes been considered conspecific with *S. hypoleucus* and *S. vieilloti*; further research, including molecular-genetic analyses, is required. Monotypic.

Distribution. Timor and Roti I, in Lesser Sundas.

Descriptive notes. 26 cm; 75–80 g. Male has head and chin to upper mantle sooty black, bare skin around eye pink or red; lower mantle and back rich yellowish olive-green with dusky streaks, rump plainer; upperwing dark, primaries with narrow whitish edging, secondaries and upperwing-coverts broadly edged olive; central tail feathers dark, suffused with olive, with whitish terminal spots on inner webs, outer tail feathers white; throat and chest olive-green, lower chest lighter olive, merging into dusky yellow then off-white on belly and undertail-coverts; iris yellow to deep red; bill black; legs grey or greenish-black. Female has

facial skin bluish-grey; plumage above brown, streaked darker on crown and upper mantle, back and rump less streaked, rump greener; wing dark, secondaries edged greenish, tail feathers dark brown with slight greenish-yellow wash and faint whitish tips; underparts creamy white, heavily streaked dark brown, buffier from throat to upper breast; iris dark brown; bill and legs greyish-green. Immature is like female, but less boldly marked. Voice. Calls include muted, slightly burred trill of two very brief phrases, duration c. 1.5 seconds.

Habitat. Primary and mature secondary deciduous monsoon forests, gallery forest, forest edges and remnants, woodlands, wooded cultivations, mangroves and scrub; generally up to 160 m, but one specimen collected in hills at 850 m.

Food and Feeding. Fruits, e.g. figs (*Ficus*). Forages alone, in pairs or in small groups in tree canopy, and lower in shrubs; often joins mixed-species flocks.

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Timor and Wetar EBA. Moderately common in parts of range, which covers 20,000–50,000 km²; within this, significant, although increasingly isolated, forest patches remain. Species' population should be monitored, as large forest areas on Timor have been converted to agriculture, mostly in lowlands and valleys, and only a few small protected (but unmanaged) areas exist. A new BirdLife-managed project is aimed at establishing Timor-Leste's first national park, probably in the Lore-L Iratalaro-Jaco I region, an Important Bird Area.

Bibliography. Coates & Bishop (1997), Hellmayr (1914), Noske (2003), Schodde & Mason (1999), Stattersfield *et al.* (1998), White & Bruce (1986).

2. Wetar Figbird

Sphecotheres hypoleucus

French: Spéciothère de Wetar **German:** Wetarfeigenpirol **Spanish:** Oropéndola de la Wetar

Taxonomy. *Sphecotheres hypoleucus* Finsch, 1898, Wetar Island, Indonesia. Original description of genus included two different spellings, “*Sphecotheres*” and “*Sphecothera*”; former selected by first reviser as the valid name for this genus. Has sometimes been considered conspecific with *S. viridis* and *S. vieilloti*, even though present species is rather distinctive; further research, including molecular-genetic analyses, is required. Monotypic.

Distribution. Wetar I, in Lesser Sundas.

Descriptive notes. 26 cm; 75–80 g. Male has pink or orange-red bare skin around eye; head, neck and upper mantle black, rest of upperparts olive-green, faintly streaked; upperwing dark, secondaries, tertials and upperwing-coverts with greenish-yellow edging; tail dark, greenish wash on central feathers, white terminal patches on inner webs of outer rectrices; chin to belly white, some olive-green on flanks; iris dark brown; bill black; legs grey. Female has facial skin bluish-grey to dark green; plumage above brown, streaked darker on crown and upper mantle, with back and rump less streaked and rump olive-green; wing dark, secondaries

edged greenish, tail dark brown, central feathers olive-green, outer rectrices with faint whitish tips; throat and underparts buff-white, heavily streaked dark brown; iris blackish; bill black; legs bright plumbeous. Immature is like female, but less boldly marked. Voice. A muted series 3–4 seconds in duration, of rather harsh, chirpy, nasal and unmusical notes.

Habitat. Primary and secondary deciduous monsoon forests, woodland and scrub; recent observations also in other disturbed habitats, such as lightly wooded scrub.

Food and Feeding. No information.

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Timor and Wetar EBA. Occurs only on the relatively small (c. 3600 km²) Indonesian island of Wetar. Although rainforest still extensive on Wetar, some recent deforestation has taken place; this species is now found mostly in NW part of the island, where it should still be moderately common. No reserves exist on Wetar, but there are proposals for one. The island is sparsely populated and only a few roads connect the largest towns, making the species relatively secure, although some poorly managed gold mines have caused severe local environmental damage. Given that the island has been visited by ornithologists only once since 1910, and then only for a few hours, the species should probably be classified as Data-deficient.

Bibliography. Anon. (2007g), Butchart & Stattersfield (2004), Coates & Bishop (1997), Collar *et al.* (2001), Finsch (1898), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), White & Bruce (1986).

3. Australasian Figbird

Sphecotheres vieilloti

French: Spéciothère de Vieillot **German:** Vieillotfeigenpirol **Spanish:** Oropéndola de Vieillot
Other common names: Figbird, Banana-bird, Mulberry-bird, Red-eye; Green/Grey-breasted/Southern Figbird (*vieilloti*); Yellow/Northern Figbird (*ashbyi*, *flaviventris*)

Taxonomy. *Sphecotheres Vieilloti* Vigors and Horsfield, 1827, near Rockhampton, east Queensland, Australia.

Original description of genus included two different spellings, “*Sphecotheres*” and “*Sphecothera*”; former selected by first reviser as the valid name for this genus. Has sometimes been considered conspecific with *S. viridis* and *S. hypoleucus*; moreover, race *flaviventris* has been treated as a separate species, but hybridizes widely with nominate in E Queensland; further research, including molecular-genetic analyses, is required. Five subspecies currently recognized.

Subspecies and Distribution.

S. v. cucullatus (Rosenberg, 1866) – Kai Is (off SW New Guinea).

S. v. salvadorii Sharpe, 1877 – SE New Guinea.

S. v. ashbyi Mathews, 1912 – N Australia (N Western Australia and N Northern Territory).

S. v. flaviventris Gould, 1850 – islands in Torres Strait and NE Australia (Cape York and NE Queensland).

S. v. vieilloti Vigors & Horsfield, 1827 – E Australia.

Descriptive notes. 27–29.5 cm; 97–146 g. Male nominate race has crown, face, ear-coverts and neck jet-black with some gloss; bare skin around eye pink or red; upper mantle grey, lower mantle, scapulars and rump olive-green; upperwing blackish-brown, outer webs of secondaries and upperwing-coverts olive-green; tail blackish, outer three feather pairs with white tip on outer web and large white terminal patch on inner web, amount of white increasing outwards, outermost rectrix with outer web almost completely white; chin, throat and chest grey, merging into olive-green on lower chest, with varying amounts of yellow and

white on belly; undertail-coverts whitish; iris deep red-brown; bill black; legs pink. Female has bare facial skin dark purple-grey; crown, neck and upper mantle brown, streaked darker, merging into less streaked olive-brown lower mantle and back, rump plain olive-green; wing dark brown, primaries narrowly edged whitish, outer webs of secondaries with green wash and edged buffy-whitish; tail brown, inner feathers washed greenish above, outer feathers with small white tips; chin to breast buff, heavily streaked brown, lower chest and belly whitish, heavily streaked brown, vent and undertail-coverts with very faint streaking; iris dark brown; bill blackish; legs dull red to pinkish-grey. Immature is like female, but less boldly marked. Races differ mainly in plumage pattern and colour, to lesser extent in size: *flaviventris* is same size as nominate, but male has glossy black head and neck sharply demarcated (no grey collar) from yellowish olive-green upperparts, and chin to belly uniformly sulphur-yellow, with some olive wash at side of breast, lower underparts whitish; *ashbyi* male resembles previous, but is brighter dorsally and rich medium-yellow ventrally, with less olive-green wash on side of breast; *cucullatus* is larger, longer-billed, with deeper yellow underparts; *salvadorii* male resembles nominate in having grey nape and breast, but is smaller, with lower chest, upper belly and flanks mostly yellow with slight orange tinge (sometimes streaked grey), all rectrices except central pair with extensive white tips. Voice. Song a hesitant series of simple tuneless whistles ending in a downslur, e.g. as “tu-tu-heer, tu-heer, tu-heer”. Calls include short sharp yelps, “pow pow pow”, and a loud “sluck”; also loud “see-kew”, repeated irregularly. Mimics other bird species, including, among others, various Psittaciformes, Pallid Cuckoo (*Cuculus pallidus*) and other oriolids.

Habitat. Various wooded and forested habitats, e.g. gallery monsoon forest, large trees along rivers, eucalypt (*Eucalyptus*) woodlands, coastal second growth, mangroves, pockets and edges of rainforest, coconut plantations, also fruiting trees, even in savannas, urban parks and gardens; distribution determined mainly by that of foodplants, especially fig trees (*Ficus*). Mainly in coastal areas; up to 500 m in New Guinea.

Food and Feeding. Mostly fruits, also some seeds and nectar; also insects, occasionally small vertebrates. Fruits include those of e.g. figs, native cherry (*Exocarpus cupressiformis*), raspberries (*Rubus*), *Lantana*, tobacco-bush (*Solanum mauritanium*), and cultivated bananas (*Musa*), pawpaws (*Asimina*), guavas (*Psidium*), loquats (*Eriobotrya japonica*), mulberries (*Morus*), and the alien inkweed (*Phytolacca octandra*). Insects mainly beetles (Coleoptera), also cicadas (Cicadidae), ants (Formicidae), termites (Isoptera) and lepidopteran caterpillars. Small lizards, e.g. common blue-tongued lizard (*Tiliqua scincoides*), taken rarely. Forages actively and noisily, sometimes alone but more often in pairs; during non-breeding season in small to large flocks of up to 100 or more individuals. Searches for food mostly high in shrubs and trees. Catches aerial insects, e.g. swarming flying ants, by aerial flycatching.

Breeding. Breeds in Oct–Feb in S of range and Sept–Mar (rarely Apr and Aug) in N; one or two broods per year. Nests in loose colonies. Co-operative breeding recorded rarely. Nest a flimsy, thin, deep saucer of vine tendrils and sometimes a few fine twigs, external diameter 12.7–15.2 cm, height 5.7–6.4 cm, internal diameter 8.9–12.1 cm, depth 5.1–5.7 cm, woven into horizontal fork near end of

branch, usually fairly high up, in densely or sparsely foliated tree, especially fig or paperbark (*Melaleuca*); in N Australia (races *ashbyi* and *flaviventris*) often close to nest of Spangled Drongo (*Dicrurus bracteatus*) or Helmeted Friarbird (*Philemon buceroides*), presumably benefiting from aggressiveness of those species. Clutch usually 3 eggs, sometimes 2 or 4, dull greyish-green to olive-brown with dark reddish-brown and purple spots or blotches concentrated at obtuse end, sometimes with larger grey halo, dimensions 29.7–36.8 × 21.2–24.6 mm; incubation by both sexes, period 16–17 days, rarely to 20 days; both also brood and feed nestlings with regurgitated food, very occasionally extra males and females (helpers) bring food to nestlings and perhaps even brood them, nestling period c. 14–17 days. Nests sometimes parasitized by Common Koel (*Eudynamis scolopacea*).

Movements. Sedentary, with local nomadic movements in search of fruiting trees; small flocks containing older individuals are less mobile, whereas larger flocks of mostly younger individuals travel farther (longest recorded movement 105 km). Populations in extreme S of range possibly migratory. Hundreds may gather at roosting sites at dusk.

Status and Conservation. Not globally threatened. Common in parts of range, which is estimated to cover c. 1,000,000–10,000,000 km². Recorded density in eucalypt woodland in New Guinea 0.2 individuals/ha. A study in N Australia (Northern Territory) showed species' presence is dependent mostly on availability of fruit and only to lesser extent on size and interconnectivity of rainforest patches. Occurs in various protected areas. Sometimes seen as a pest in commercial orchards.

Bibliography. Barrett *et al.* (2003), Bèland (1977), Bell (1983c), Beruldsen (1980), Blakers *et al.* (1984), Coates (1990), Coates & Bishop (1997), Crouther (1985), Dickinson (2004), Dunning (2008), Ford, J.R. Genus *ORIOLOS* Linnaeus, 1766

4. Brown Oriole

Oriolus szalay

French: Lorient papou

German: Grantpirol

Spanish: Oropéndola Papú

Other common names: Striated/New Guinea Oriole

Taxonomy. *Mimeta szalay* Madarász, 1901, Finschhafen, Huon Gulf, north-east New Guinea. Forms a superspecies with *O. phaeochromus*, *O. forsteni*, *O. bouroensis*, *O. melanotis* and *O. sagittatus*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Monotypic.

Distribution. New Guinea and West Papuan Is (Waigeo, Batanta, Salawati, Misool).

Descriptive notes. 25–28 cm; 79–115 g. Visual and vocal mimic of Helmeted Friarbird (*Philemon buceroides*), and is itself mimicked visually and vocally by Streak-headed Honey-eater (*Pycnopygius stictocephalus*). Plumage is medium-brown above, paler on head, heavily streaked with black on crown, less so on mantle; face and ear-coverts black, streaked whitish, contrasting with lighter side of neck and hindcrown; upperwing dark brown; tail dark brown, all except central feathers with indistinct paler tips on inner webs; buff below, chin, throat and chest heavily streaked black, belly less heavily so; iris deep red-brown; bill blackish. Sexes alike. Immature has prominent white supercilium and tawny edges of upperwing-coverts; iris brown, bill black. Voice. Varied short, loud phrases including fluty whistles, beginning with one or two pairs of descending short notes and ending with rising disyllabic slur, “titu-witu-whiew”, “tip-top-tertert” or “nn-dudu-tiew”; also a friarbird-like “du-du-hoo”, and clear vocal mimicry of many other bird species. Other calls include high-pitched falling and rising “hiiewee” whistle, sometimes “ch-hiiewee”, “prrr-hiiewee” or “trr-oooueei”; also 1–2 descending notes followed by longer downslurred note “(dop)-dop-houw”. Duetting common but poorly synchronized, one bird giving lower-pitched friarbird-like phrase and the other high-pitched loudly whistled notes.

Habitat. Mainly disturbed areas, e.g. forest edges and second growth; also lowland and foothill rainforests, monsoon forest, swamp-forest, gallery forest and scrub, dense savannas, mangroves, and plantations, e.g. teak (*Tectona*), rubber, *Aracaria* pine, and gardens. Lowlands to 1850 m, usually below 1200 m.

Food and Feeding. Fruits, insects (e.g. caterpillars, pupae), also some grass seeds and probably nectar. Forages alone, in pairs or in small groups, mainly in canopy.

Breeding. Nest-building reported in Aug–Sept, egg-laying in Apr–May and Sept–Nov, brooding adult in Apr, nestlings in Jan and fledgling in Sept. Rough open cup-nest woven from bark strips and sometimes also bark flakes and other fibres, lined with fine grasses and small stems, suspended hammock-like from thin, horizontal forked branch 2.5–15 m above ground; often near colony of Helmeted Friarbirds, and sometimes near Hooded Butcherbird (*Cracticus crassius*) nest. Clutch 1–2 eggs, brownish yellow-white with chocolate-brown, olive-brown and greyish spots concentrated on obtuse end, dimensions 31–32.3 × 20.9–22.8 mm; nestlings fed with fruits and probably larvae; no information on duration of incubation and nestling periods.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Common in parts of range, which estimated to cover c. 100,000–1,000,000 km². Estimated densities of 0.4 individuals/ha in lowland rainforest and 0.07 individuals/ha in coastal savanna.

Bibliography. Beecher (1978a), Beecher *et al.* (1986), Clapp (1986a, 1990), Coates (1990), Diamond (1972a), Dunning (1993, 2008), Majnepe & Bulmer (1977), Mees (1965a), Rand & Gilliard (1967), Schönwetter & Meise (1983), Stresemann & Paludan (1932a).

5. Dusky-brown Oriole

Oriolus phaeochromus

French: Lorient d'Halmahera

German: Halmaherapirol

Spanish: Oropéndola de Halmahera

Other common names: Halmahera/Dusky/Ruddy/Moluccan/Gray's Oriole

Taxonomy. *Oriolus phaeochromus* G. R. Gray, 1861, Halmahera Is., Indonesia.

Forms a superspecies with *O. szalay*, *O. forsteni*, *O. bouroensis*, *O. melanotis* and *O. sagittatus*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Monotypic.

Distribution. Halmahera, in N Moluccas.

Descriptive notes. 26 cm. A close visual mimic of Dusky Friarbird (*Philemon fuscicapillus*), from which difficult to distinguish in the field. Plumage is more or less uniformly plain dark brown throughout, slightly paler and greyer on forehead, chin to chest and sides of neck, and flight-feathers and tail; primaries edged pale brown; iris dark brown; bill and legs black. Sexes alike. Immature undescribed. Voice. Not certainly recorded; call attributed to this species a moderately loud, liquid, 2-note whistle 0.75 seconds in duration (preceded by almost inaudible “k’k’-wheou”), repeated at intervals of c. 8 seconds.

Habitat. Primary forest and mature secondary forest from lowlands up to 1200 m; found also in agricultural and other cultivated lands.

Food and Feeding. Arthropods and small fruits. Forages alone or sometimes in pairs, from middle storey to canopy; sometimes joins mixed-species flocks.

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Northern Maluku EBA. Moderately common to frequent in parts of its range of c. 20,000–50,000 km². Extensive forest tracts remain on Halmahera, and the Aketajawe-Lolobata National Park, covering 1673 km² of hill and lowland rainforest of exceptional biodiversity importance, was declared in 2004; several other protected areas have been proposed. Most of the remaining forest, however, is covered by timber concessions, and plans for agricultural development further endanger the long-term future of Halmahera's forest habitats.

Bibliography. Coates & Bishop (1997), Heinrich (1956), Meinertzhagen (1923), Poulsen & Lambert (2000), Salvadori (1875), Stattersfield *et al.* (1998), White & Bruce (1986).

6. Grey-collared Oriole

Oriolus forsteni

French: Lorient de Céram

German: Forstenpirol

Spanish: Oropéndola de Seram

Other common names: Seram/Ceram/Forsten's/Grey-necked Oriole

Taxonomy. *Mimeta forsteni* Bonaparte, 1850, Seram, south Moluccas.

Forms a superspecies with *O. szalay*, *O. phaeochromus*, *O. bouroensis*, *O. melanotis* and *O. sagittatus*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Monotypic.

Distribution. Seram, in S Moluccas.

Descriptive notes. 31 cm; 105–113 g. A close visual mimic of Seram Friarbird (*Philemon subcorniculatus*), from which very difficult to distinguish in the field. Plumage is olive-brown above, crown paler with dark streaking and separated from unstreaked darker olive mantle by grey nuchal collar; side of face darker grey-brown, area of greyish bare skin around eye; upperwing dark olive, remiges edged greenish-yellow; tail dark olive-brown, paler and greyer on underside, with paler tips on inner webs; chin and throat grey-green with darker streaks; chest warm golden-olive, mottled darker and merging into paler buffy belly and undertail-coverts; iris light brown to reddish-brown; bill black; legs blackish-brown. Sexes alike. Immature undescribed. Voice. Poorly known; calls said to be made by this species are a series c. 1 second in duration of 3–4 rising musical notes with liquid, warbling quality, repeated at intervals of 6–7 seconds; also a drawn-out melodious disyllabic whistle, repeated at intervals of 3–4 seconds for long periods; also a fluted 2-note “whee-who”, second note lower than first; single nasal downslur; short unmusical notes more or less identical to those of Seram Friarbird.

Habitat. Occurs in lowland and montane primary forest, up to 1100 m; less common at higher altitudes.

Food and Feeding. Stomach contents of specimens included many insect remains, also some remains of fleshy red fruits and their seeds. Forages alone or in pairs, from middle storey to canopy; sometimes joins mixed-species flocks.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Seram EBA. Moderately common to frequent in parts of its range, which covers 20,000–50,000 km². Not currently at risk as Seram is still well forested, although some coastal lowland forests have been cleared. Potential threats include timber extraction, oil-drilling operations, and hydro-electricity schemes. Manusela National Park protects c. 10% of Seram's land area and all of its forest ecosystems.

Bibliography. Bowler & Taylor (1989a), Coates & Bishop (1997), Meinertzhagen (1923), Stattersfield *et al.* (1998), Stresemann (1914a).

7. Black-eared Oriole

Oriolus bouroensis

French: Lorient de Buru

German: Burupirol

Spanish: Oropéndola de Buru

Other common names: Dark-eared/Black-faced/Buru Oriole; Tanimbar Oriole (*decipiens*).

Taxonomy. *Philedon bouroensis* Quoy and Gaimard, 1830, Buru Island, south Moluccas.

Forms a superspecies with *O. szalayi*, *O. phaeochromus*, *O. forsteni*, *O. melanotis* and *O. sagittatus*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Two subspecies recognized.

Subspecies and Distribution.

O. b. bouroensis (Quoy & Gaimard, 1830) – Buru, in S Moluccas.

O. b. decipiens (P. L. Slater, 1883) – Tanimbar Is, in E Lesser Sundas.

Descriptive notes. 23–32 cm. A close visual mimic of Black-faced Friarbird (*Philemon moluccensis*), from which it is difficult to distinguish in the field. N nominate race has blackish-brown facial patch with pale whitish-brown superciliary stripe, whitish side of neck behind ear-coverts; otherwise dark brown above, including wing and tail, with darker streaking on crown, paler terminal spots on tail (barely visible); paler below, chin and throat whitish with darker streaking, chest and rest of underparts plain tawny-olive; iris reddish-brown; bill black; legs black, toes lead-grey. Sexes alike. Immature has rufous edges on

wing feathers. Race *decipiens* differs from nominate in having black ear patch less developed, faint grey nuchal collar, heavier streaking (almost spotted) on throat, and is darker brown below. **VOICE.** N nominate race said to mimic Black-faced Friarbird, but voice not certainly recorded. Race *decipiens* has a single rich, slightly drawn-out, downslurred musical note, loud and clear, repeated at intervals of 12–30 seconds; also a disyllabic whistle, first part of which is nasal and somewhat grating, second part resembling the call, repeated at 12–20 seconds; also described as a clear whistle dropping in pitch, then quickly inflected upwards again, typical of genus.

Habitat. Lowland and montane forests, deciduous monsoon forest, secondary woodland, mangroves, and lightly wooded cultivation, to 1460 m.

Food and Feeding. No information on dietary details. Forages alone or in pairs, often together with Black-faced Friarbirds.

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Banda Sea Islands EBA and in Buru EBA. Moderately common in parts of its range, which extends over c. 20,000–50,000 km². Most forests in Tanimbars still remain, although a logging concession covers S Tanimbar; the small Nustamar and Pulau Nuswotar Nature Reserves protect some forests in these islands. On Buru, most coastal lowland forests have been cleared, and forests in N of island have been degraded by selective logging and slash-and-burn agriculture, leaving few patches of lowland forest intact, while montane forests remain largely undisturbed. No protected area exists on Buru, although the proposed Gunung Kelapmatada Game Reserve would protect large areas of both lowland and montane forests.

Bibliography. Bishop & Brickley (1999), Coates & Bishop (1997), Dickinson (2004), Hartert (1900c, 1901), Jepson (1993a), Meinertzhagen (1923), Poulsen & Lambert (2000), Slater (1883), Siebers (1930), Stattersfield *et al.* (1998), Stresemann (1914b), Wallace (1863).

8. Olive-brown Oriole

Oriolus melanotis

French: Loriot de Timor

German: Sundapirol

Spanish: Oropéndola Olivácea

Other common names: Timor/Sunda/Dark Oriole

Taxonomy. *Mimeta melanotis* Bonaparte, 1850, “Nova Guinea” = Timor.

Species sometimes referred to by the name *O. viridifuscus*, but current name has priority over that. Forms a superspecies with *O. szalayi*, *O. phaeochromus*, *O. forsteni*, *O. bouroensis* and *O. sagittatus*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Birds of this species on Atauro I, off N Timor, of uncertain racial affinity, provisionally placed with *finschi* but possibly an undescribed race; further study required. Two subspecies recognized.

Subspecies and Distribution.

O. m. finschi E. J. O. Hartert, 1904 – Wetar I and Atauro I, in Lesser Sundas.

O. m. melanotis (Bonaparte, 1850) – Timor, Roti and Semau, in Lesser Sundas.

Descriptive notes. 25 cm. Female is a visual mimic of Helmeted Friarbird (*Philemon buceroides*), but male less so (race *finschi*) or not at all (nominate). Male nominate race is dark olive above, crown and mantle with faint darker streaking; upperwing dark brown, coverts fringed pale; tail dark brown, underside paler, feathers with whitish terminal patches on inner webs; face blackish, throat and chest greyish, side of chest washed olive-green, belly and undertail-coverts grey-buff; iris red; bill dark red; legs dark grey. Female is lighter brown above than male, rump paler, crown streaked darker brown, whitish supercilium

behind eye; face and side of neck black; dirty white below, streaked brown, especially on breast; bill blackish-brown. Immature is like female, but with more chest streaking. Race *finschi* resembles female of nominate but lacks olive wash above, male slightly darker and with upperparts greyer, both sexes with head pattern less distinct, face, ear-coverts, chin and throat darker than nominate, rest of underside medium-brown, iris light brown. **VOICE.** Utters liquid whistles, e.g. “ti-ti-lu-i”, but with many variations; also a long ringing “ti-u”, two individuals often call antiphonally, at intervals of 6–7 seconds. Calls on Atauro I described as “wee-oww” or “wee-ole”, “wick-wick wow” and “sweet-ow”, apparently different from those of nominate race.

Habitat. Remnant patches of primary and secondary deciduous monsoon forests, open woodland, mangroves, partially wooded cultivation, and other disturbed habitats, to 300 m. On Atauro I found in closed-canopy forest from sea-level to 970 m, and especially common in montane forest above 750 m.

Food and Feeding. No information on diet. Forages alone or in pairs, from middle storey to canopy.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Restricted-range species: present in Timor and Wetar EBA. Generally uncommon and rather sparsely distributed within its range of 20,000–50,000

km². In 2004 found to be common, and abundant at higher elevations, on Atauro I. Although significant, but increasingly isolated, forest patches remain in this species’ range, its population should be monitored, as large areas of forest on Timor, mostly in lowlands and valleys, have already been converted to agriculture; only a few small protected (but unmanaged) areas exist on Timor, and none on Wetar. A new BirdLife-managed project is aimed at establishing Timor-Leste’s first national park, probably in the Lore–L Lalalalo–Jaco I region, an Important Bird Area.

Bibliography. Coates & Bishop (1997), Finsch (1898), Hellmayr (1914), Mayr (1944a), Stattersfield *et al.* (1998), Trainor & Soares (2004), White & Bruce (1986).

9. Olive-backed Oriole

Oriolus sagittatus

French: Loriot sagittal

German: Streifenpirol

Spanish: Oropéndola Estriada

Other common names: Australian/Green-backed/Northern/White-bellied Oriole, Green Oriole(!), Cedar Bird, Green Thrush

Taxonomy. *Coracias sagittata* Latham, 1801, “Nova Wallia Australi” = Sydney, Australia.

Forms a superspecies with *O. szalayi*, *O. phaeochromus*, *O. forsteni*, *O. bouroensis* and *O. melanotis*, all of which, together with more distantly related *O. flavocinctus*, were formerly placed in the alternative genus *Mimeta* on basis of skull characteristics. Races probably intergrade, but more study needed. Four subspecies recognized.

Subspecies and Distribution.

O. s. magnirostris van Oort, 1910 – SC New Guinea.

O. s. affinis Gould, 1848 – NW and NC Australia (E to S Gulf of Carpentaria).

O. s. griseescens Schodde & Mason, 1999 – NE Australia (Cape York, in N Queensland).

O. s. sagittatus (Latham, 1801) – NE Australia (except Cape York) S to Victoria and SE South Australia; many migrate N in winter.

Descriptive notes. 25–28 cm; 93.5–104 g. Male nominate race has head and upperparts rich olive-green, mantle and scapulars finely streaked black, uppertail-coverts olive-grey, spotted whitish (when plumage fresh); upperwing feathers bluish-grey with blackish centres, edged and tipped cream or whitish; tail grey, paler on outer webs of feathers, with greenish wash above, paler below, with conspicuous large white terminal patches on inner webs; chin and throat olive-washed grey with narrow blackish streaks, underparts creamy or white, heavily streaked black, side of breast washed olive, vent and undertail-coverts plain white or nearly so; iris

red or orange; bill orange-red to deep pink; legs grey or blue-grey. Female is greyer and more heavily streaked above than male, including on crown; wing has cinnamon edging and tail has cinnamon wash on white feather tips; chin grey, and side of throat more heavily streaked. Immature has olive-grey crown and upperparts, narrow buff eyebrow and eyering; wing and tail dull brown, wing feathers all edged cinnamon and with light cinnamon-buff wash on underwing, tail with whitish tips smaller than adult’s; breast and belly white, strongly streaked black; iris dark brown, bill dark brown to dark grey. Race *affinis* is slightly smaller than nominate, with longer and more slender bill, male generally brighter green and with faint streaking above, less heavily streaked below, tail spots small; *griseescens* is smaller still but with long and slender bill, male much greyer above and distinctly streaked, tail spots medium-sized; *magnirostris* is smallest and is paler, with uniform heavy wedge-shaped streaks above, tail spots small. **VOICE.** Song of rich, varied and melodious loud whistles based on “orry-orry-ole” or “or-ee-ee”; subsong quieter. Calls include harsh notes and a sneezing “chee-et”; various squeaks and chatters uttered during foraging. An excellent mimic of other birds.

Habitat. Most semi-open wooded areas, e.g. eucalypt (*Eucalyptus*) forests and paperbark (*Melaleuca*) woodlands, also native tree plantations, rainforest edges, and large trees alongside rivers and in savannas, parks and gardens; sometimes in mangroves.

Food and Feeding. Fruits, berries and small arthropods, also seeds and nectar; nestlings of small birds taken rarely. Berries, fruits and seeds include those of e.g. alien mulberries (*Morus*), inkweed (*Phytolacca octandra*) and Japanese peppers (*Zanthoxylum*), native olives (*Olea*), berries of white cedar (*Melia azedarach*), of camphor laurel (*Cinnamomum camphora*) and of the mistletoe *Amyema cumbagei*, but especially figs (*Ficus*); sometimes raids grape (*Vitis*), cherry (*Prunus*), peach (*Prunus persica*), banana (*Musa*) and paw-paw (*Asimina*) orchards. Arthropods taken include spiders (Araneae) and insects such as e.g. leaf beetles (Chrysomelidae), ants (Formicidae), mantids, lepidopteran caterpillars. Forages alone or in pairs, during non-breeding season also in small flocks; sometimes joins foraging groups of *Speothoerpes vielloti*. Feeds mainly in canopy, sometimes descending to ground. Animal items obtained mostly by gleaning from twigs and foliage; sometimes captures insects by aerial flycatching, and takes nestlings of e.g. honeyeaters (Meliphagidae).

Breeding. Breeds in all months, mainly Aug–Jan; sometimes two broods. Territorial, sings regularly throughout year. Nest built by female, within period of 2 weeks, a deep cup-shaped structure woven from bark strips, leaves, vine tendrils, grasses, plant wool, hair and other soft plant materials, lined with softer grasses and bark, often decorated with spider webs, bark or bearded lichen (*Usnea barbata*), external diameter 14–19.1 cm, height 10.2–15.2 cm, internal diameter 8.3–11.4 cm, depth 6.4–7.6 cm, bound with cobweb to thin horizontal fork in outer foliage of tree or shrub at variable height; often nests in or near colonies of *Speothoerpes vielloti*. Clutch 2–3 eggs, sometimes 4, creamy yellowish-white to pale creamy brown with greyish, purplish-grey and brownish-olive spots and blotches sometimes concentrated at obtuse end, dimensions 31–38 × 21–25 mm; incubation by female, period 16–18 days; chicks fed by both parents, with regurgitated food, fledge after 15–17 days; young disperse as soon as they become independent; if two broods, male may take care of older fledglings while female begins second nest. Nest sometimes parasitized by Common Koel (*Eudynamis scolopacea*).

Movements. In most of range locally nomadic in response to food-supply fluctuations. In S of range (S of c. 27° S), many (not all) individuals migrate N to C & NE Queensland in autumn (when vagrants recorded even in unusually dry habitats), returning S in spring; longest recorded movement 644 km. Possibly some limited movement between Australia and S New Guinea, perhaps by migrants moving N from SE Australia. Single vagrants recorded on Luang, in E Lesser Sundas (in 1905), and on New Britain, off NE New Guinea.

Status and Conservation. Not globally threatened. Common in parts of its range, which estimated to cover 1,000,000–10,000,000 km². Recorded densities 0.02–1 individuals/ha. Occurs on forest patches larger than 5 ha in extent, although sometimes visits smaller patches. Dependent in various protected areas, and therefore not reckoned to be at any immediate risk. Sometimes considered a pest in gardens and commercial orchards, where it takes soft fruits.

Bibliography. Barrett *et al.* (2003), Béland (1977), Beruldsen (1980), Blakers *et al.* (1984), Coates (1990), Frith (1969), Hall & Carline (1974), Higgins *et al.* (2006a), Klapste (1982), Liddy (1982b), Loyn (1985b), Macdonald (1973), Mathews (1926), North (1902), Rand & Gilliard (1967), de Ruiter (1995), Schodde & Mason (1999), Schodde & Tidemann (1990), Schönwetter & Meise (1983), Simpson *et al.* (2004), Slater *et al.* (2003), Sontner (1984).

10. Green Oriole

Oriolus flavocinctus

French: Lorient verdâtre **German:** Mangrovepirol **Spanish:** Oropéndola Verdosa
Other common names: Yellow-bellied/(Australian) Yellow Oriole

Taxonomy. *Mimetes* [sic] *flavocinctus* P. P. King, 1826, Northern Territory, Australia.

Was formerly placed, together with superspecies formed by *O. szalayi*, *O. phaeochromus*, *O. forsteni*, *O. bouroensis*, *O. melanotis* and *O. sagittatus*, in the alternative genus *Mimeta* on basis of skull characteristics. Geographical variation poorly marked and races intergrade; races *migrator* and *muelleri* considered untenable by some authors, or sometimes species even treated as monotypic. Six subspecies currently recognized.

Subspecies and Distribution.

O. f. migrator E. J. O. Hartert, 1904 – Roma, Leti and Moa, in E Lesser Sundas.

O. f. muelleri (Bonaparte, 1850) – Aru Is and SC New Guinea.

O. f. flavocinctus (P. P. King, 1826) – N Western Australia (Kimberley) and Northern Territory (Arnhem Land and Groote Eylandt).

O. f. tиви Schodde & Mason, 1999 – Bathurst I and Melville I (off NW Northern Territory).

O. f. flavotinctus Schodde & Mason, 1999 – NE Australia (Cape York Peninsula, in N Queensland).

O. f. kingi Mathews, 1912 – coastal zone of NE Queensland from Trinity Bay S to Halifax Bay.

Descriptive notes. 25–30 cm; male 83–125 g, female 73–116 g. Male nominate race is yellowish-olive above, with light dusky streaking on crown, heavier streaking on mantle; lores dark; upperwing dark, wing-coverts edged and broadly tipped creamy white to yellow (appearing as wingbars on folded wing), secondaries and greater coverts edged greenish-olive; tail blackish-brown, feathers tipped creamy white to yellow, pale tips larger on inner webs; chin olive, mottled dark, throat and chest olive with dark streaks, becoming lighter and yellower and variably streaked on lower breast and belly; undertail-coverts pale

yellow with greyish-olive feather centres (appearing variably mottled); iris red to bright orange; bill orange or red; legs grey. Female resembles male, but duller and rather more streaked. Immature has narrow yellow supercilium, more heavily streaked crown, nape and back, back duller green, underparts yellower, heavier black streaks from chin to upper belly, and yellow tail tips smaller;

eye grey-brown, bill blackish. Race *flavotinctus* is larger than nominate, much brighter yellow, and much less heavily streaked above, with large yellow tail tips; *kingi* also is large, but paler yellow than previous and moderately spotted; *tivi* is slightly smaller than nominate, slightly duller yellowish-olive, including on belly, with bolder blackish-brown or blackish streaking on crown and upperparts, slightly bolder blackish-brown streaking on underparts; *migrator* resembles last, but with smaller yellow tail tips; *muelleri* is poorly known, is smaller than nominate, with edgings and tips of wing-coverts pure white. **VOICE.** Song a melodious roll of 3–4 loud bubbling notes, e.g. as phrase of 3 notes the last of which a gurgling sound, or as liquid “cholonk cholonk”; also a soft warbling subsong. Call a harsh sneezing sound and loud 2-note sneer.

Habitat. Rainforest, gallery forest, gallery scrub forest, lightly wooded cultivation, coastal brush, and vine thickets, especially those along permanently running streams; usually in wetter and more closed forest habitats than those occupied by *O. sagittatus*. Dispersing young may also be found in more marginal habitats, such as mangroves, paperbark (*Melaleuca*) galleries, parks, orchards and gardens, and they often move inland along streams, whereas majority of population is found in coastal areas.

Food and Feeding. Chiefly fruits, also some seeds and nectar; some insects; rarely, nestlings of small birds. Berries and fruits include especially figs (*Ficus*), but also paw-paws (*Asimina*), and alien mulberries (*Morus*) and Japanese peppers (*Zanthoxylum*), among others. Insects recorded in diet are the ant *Oecophylla smaragdina* and lepidopteran caterpillars. Recorded as taking Olive-backed Sunbird (*Cinnyris jugularis*) nestlings as food in NE Australia. Forages alone, in pairs or in small groups, from middle storey to canopy; visits orchards. Sometimes small groups of up to eight individuals gather in fruiting trees, especially towards end of dry season when resources are scarce. Sometimes joins foraging *Sphecotheres vieilloti* and Great Bowerbird (*Chlamydera nuchalis*) groups, especially in fruiting trees.

Breeding. Breeds Aug–Jan, sometimes Feb–Mar and Jul; probably single-brooded. Male sings throughout year to mark territory. Deep cup-shaped nest woven from bark fibres, grasses, leaves, twigs and vine tendrils, lined with wool, hair and finer plant material, external diameter 12.7–20.3 cm, height 7.6–12.7 cm, internal diameter 7.6–10.2 cm, cup depth 5.1–7.6 cm, bound with cobweb to thin horizontal fork 2–20 m above ground in outer tree branches, often overhanging water. Clutch 2–3 eggs, creamy yellowish-white to pale creamy brown with greyish, purplish-grey and blackish-brown spots and blotches concentrated at obtuse end, dimensions 31–35 × 21.8–24 mm; incubation of eggs and brooding of chicks mainly by female, male helping occasionally, but both sexes feed chicks with regurgitated food; no information on duration of incubation and nestling periods; fledglings remain with parents in family group for a few weeks.

Movements. Mainly sedentary. Dispersing young may roam widely, with wanderers recorded in wet forests and mangroves; no records in extreme W part of range in Mar–May and Dec–Feb.

Status and Conservation. Not globally threatened. Common in parts of its range, which estimated to cover 100,000–1,000,000 km². Occurs in various protected areas, and not therefore at any immediate risk. Is, however, to some degree dependent on large tracts of undisturbed rainforest, and apparently cannot survive in small and isolated rainforest remnants.

Bibliography. Barrett *et al.* (2003), Beruldsen (1980), Blakers *et al.* (1984), Coates & Bishop (1997), Dunning (2008), Hall & Carline (1974), Higgins *et al.* (2006a), Mathews (1926), Meinertzhagen (1923), Merrall (1987), North (1902), Price *et al.* (1999), Rand & Gilliard (1967), Schodde & Mason (1999), Schodde & Tidemann (1990), Schönwetter & Meise (1983), Simpson *et al.* (2004), Slater *et al.* (2003).

11. Dark-throated Oriole

Oriolus xanthonotus

French: Loriot à gorge noire **German:** Gelbmantelpirol **Spanish:** Oropéndola Gorjinegra
Other common names: Black-headed/Black-throated/Malaysian Oriole

Taxonomy. *Oriolus xanthonotus* Horsfield, 1821, Java.

Sister-species to and formerly treated as conspecific with *O. steerii*, both possibly forming a superspecies with *O. isabellae*; all three were formerly placed in the alternative genus *Xanthonotus*. Proposed race *palawanus* has same type locality (Puerto Princessa, on Palawan) as *persuasus*, of which it is a junior synonym. Four subspecies recognized.

Subspecies and Distribution.

O. x. xanthonotus Horsfield, 1821 – extreme S Myanmar (S Tenasserim), S Thailand, Peninsular Malaysia, Sumatra, Bangka, Java and SW Borneo.

O. x. mentawi Chasen & Kloss, 1926 – Mentawai Is (Siberut, Sipura, Pagai Is), off W Sumatra.

O. x. persuasus Bangs, 1922 – Culion I and Palawan, in W Philippines.

O. x. consobrinus R. G. W. Ramsay, 1880 – N, C & E Borneo and adjacent islands.

Descriptive notes. 17.5–19 cm; 30–48 g. Male nominate race has head to neck, upper mantle and breast all black, rest of mantle to uppertail-coverts golden-yellow; upperwing black, primaries narrowly fringed whitish, secondaries indistinctly edged yellowish; tail black, all except central feathers with yellow terminal patch on inner webs; border of black chest tinged yellow on sides, belly creamy white and heavily streaked black, undertail-coverts golden-yellow; iris blood-red; bill dull orange, red or red-brown; legs blue-grey. Female has crown olive, lightly streaked greyish, mantle yellowish-olive and rump yellower, uppertail

olive-green; upperwing dark, primaries edged whitish, secondaries, tertials and upperwing-coverts dull olive, fringed brighter olive; whitish or creamy below, throat and breast suffused with dark grey, belly heavily streaked dark brown (almost as heavily as on male), blacker on flanks, undertail-coverts yellow, undertail as male. Immature is like female, but throat whitish and only faintly streaked, rufous edges on greater upperwing-coverts, iris pinkish. Race *mentawi* is smaller than nominate, and female has darker crown with much broader blackish feather centres; *consobrinus* is larger than nominate, male greener above, yellow tips on rectrices larger, lacks yellow wash on side of black chest, female has darker grey-green (sometimes blackish) crown contrasting more strongly with mantle than in nominate female; *persuasus* male is like previous in lacking yellow wash bordering black breast, but has underparts greyer (not creamy white). Voice. Song a rich and melodious fluty “tu-u-liu” with upward inflection on last note; also as 4-note “peu-peu-peu-poh”, the first 3 notes level and with liquid and melodious quality, the last a descending nasal rasp; also as “eeeeee-yopp” or “kou-wit”, first syllable rising and second descending, repeated every 2–4 seconds, sometimes for several minutes, accompanied by tail-flicking. Call a descending “phee-u”.

Habitat. Primary and tall secondary evergreen forests, e.g. mixed dipterocarp forest, also forest edges, second growth, kerangas, tall plantations, peatswamp-forest, and tall trees in clearings. To 1220 m, usually below 300 m.

Food and Feeding. Berries, e.g. of jambu tree (*Eugenia jambos*) and fig trees (*Ficus*); also insects, e.g. fly larvae (Diptera) and adult and larval moths and butterflies (Lepidoptera). Forages alone or in pairs, from middle storey to canopy; sometimes joins mixed-species flocks.

Breeding. Nesting recorded in May in extreme S Thailand (Narathiwat), and in Feb (Perak) and Jun (Johor) in Peninsular Malaysia, where also begging juveniles in Aug (Negeri Sembilan); nestling in Jun in Sumatra (Bengkulu); season Feb–Aug/Sept in Borneo; males with enlarged gonads in Apr–May in Philippines. Two nests from Perak were each a deep open-cup structure of grasses and bamboo and other leaves, suspended hammock-like high in forest-edge tree, one on a creeper and the other on a branch; one nest in N Borneo (Sabah) was composed of fine pliable twigs, strips of paper-like bark and other vegetable fibres, lined with finer material, exterior decorated with pieces of lichen and spider cocoons or egg sacs, slung between twigs of a forked outer branch 6 m above ground in a flamboyant tree (*Delonix regia*). Clutch 2 eggs, white to pale creamy pink, with yellowish-brown, chestnut-brown or dark purplish-brown spots with underlying lavender concentrated at obtuse end, dimensions 24.8–26 × 17.8–19.8 mm; both adults incubate. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Fairly common and widespread in evergreen forests. Despite its relatively large area of distribution, habitat loss, degradation and fragmentation in its range have been so extensive, especially in lowlands, that almost all primary forests expected to have disappeared by 2010. Although it utilizes submontane and secondary forests and forest edges, which are less threatened, this species' abundance is lower in these habitats than in its core lowland-forest habitat. Owing to habitat loss, it has been extinct in Singapore since 1941 and is much reduced in Thailand and Peninsular Malaysia, where it is considered “Vulnerable”. Sometimes sold in cagebird trade. Occurs in various protected areas, e.g. Hala-Bala Wildlife Sanctuary, in Thailand, Taman Negara National Park and Pondok Tanjung Forest Reserve, in Peninsular Malaysia, Way Kambas National Park, in Sumatra, Gunung Gading National Park and Danum Valley Conservation Area, in Borneo, and St Paul Subterranean River National Park, in Philippines.

Bibliography. Anon. 12. Philippine Oriole

Oriolus steerii

French: Loriot des Philippines **German:** Philippinenpirol **Spanish:** Oropéndola Filipina

Other common names: Grey-throated Oriole; White-lored Oriole (*albiloris*)

Taxonomy. *Oriolus steerii* Sharpe, 1877, Negros and Basilan = Negros, Philippines.

Sister-species to and formerly treated as conspecific with *O. xanthonotus*, both possibly forming a superspecies with *O. isabellae*; all three were formerly placed in the alternative genus *Xanthonotus*. Race *albiloris* sometimes treated as a separate species, with closer relationship to *O. isabellae*; sometimes misspelt “*albiloris*”. Proposed race *O. s. nigrostriatus* (from Negros and Masbate) is synonymized with nominate. Six subspecies recognized.

Subspecies and Distribution.

O. s. albiloris Ogilvie-Grant, 1894 – mountains of N & WC Luzon (provinces of Benguet, Cagayan, Ilocos Norte, Nueva Ecija and Bataan), in N Philippines.

O. s. steerii Sharpe, 1877 – Masbate and Negros, in C Philippines.

O. s. assimilis Tweeddale, 1878 – Cebu, in C Philippines.

O. s. samarensis Steere, 1890 – Samar, Leyte, Bohol and E Mindanao, in EC & SE Philippines.

O. s. basilanicus Ogilvie-Grant, 1896 – Basilan and W Mindanao, in S Philippines.

O. s. cinereogenys Bourns & Worcester, 1894 – Sulu Archipelago (Tawi-Tawi and Bongao, possibly also Baliungan).

Descriptive notes. 18–20 cm; 45–48 g. Nominant race has crown, neck and most of upperparts bright olive-green, rump yellow; lores grey, ear-coverts washed greenish; upperwing grey, primaries edged greyish-white, secondaries dull greenish, wing-coverts grey; central tail feathers blackish-green, other rectrices black with yellow terminal patch on inner webs; chin, throat and upper breast uniform grey, lower breast and belly white, boldly streaked black, undertail-coverts yellow; iris red; bill dark red or red-brown; legs dark grey. Sexes alike, female slightly smaller than male. Immature undescribed. Race *assimilis* is uni-

formly darker olive-green above than nominate, has lower breast and belly greyer, ear-coverts dark grey, tail all black with only very small terminal yellowish-white spots on inner webs; *samarensis* is yellower above than nominate, so that rump only slightly yellower than mantle and back, has upper chest paler grey and slightly mottled brown, lower chest and flanks washed with yellow, wing-coverts and edging of remiges concolorous with back; *cinereogenys* is similar to previous, but yellower above, especially on rump (which also streaked with olive), ear-coverts grey (not grey-green), much whiter below, but streaked greyish on chin, throat and upper breast; *basilanicus* is similar to nominate but rather smaller, and rump duller yellow; *albiloris* is distinctive, upperparts uniformly yellowish-olive, lores whitish, chin white, throat and underparts uniformly yellow, lightly streaked with olive on lower chest and flanks, wing dark, remiges edged yellowish-olive and inner edges of secondaries yellowish, tail yellow-olive above and yellower below, all except central pair of rectrices tipped broadly yellow on inner web and narrowly yellow on outer web. Voice. Loud, hollow and melodious. Nominant race has trumpet-like high-pitched “per-jek”, repeated continuously but speeding up, and a resonant “eeerk eeerk eeerk” or “kok-kok-kok-kok”; also “hoouoo-op”, first note rising slightly. Race *albiloris* a fluty, slightly mournful slow “chow-wooooo”, final note rising, repeated every 2 seconds; also a rapid staccato “chup chup chup” (3–6 notes), repeated continuously. Variety of other calls, all fluty and rhythmic, e.g. “da de hoouu”, “chit-di-di hoouoi” and “chip wuuu wu”.

Habitat. Forest, forest edge and second growth, below 1200 m.

Food and Feeding. No information on diet. Forages alone, in pairs or in small flocks, mainly in canopy; sometimes joins mixed-species flocks.

Breeding. Birds with enlarged gonads in May–Jun and almost grown young seen in Aug on Luzon (race *albiloris*). No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Race *albiloris* (sometimes treated as separate species) a restricted-range taxon: present in Luzon EBA. Species is fairly common to common in parts of its range, which extends over an estimated 100,000–1,000,000 km². Race *assimilis* was thought probably extinct; last recorded on Cebu in 1906, but unconfirmed reported sighting there in 2000. Although relatively large forest tracts remain in N Luzon, where race *albiloris* can also utilize degraded forests, this race presumed to have undergone a population decline since only c. 25% of original forest cover on Luzon remained by 1988, with lowland forests particularly affected, and most surviving forest areas under logging concessions; even montane forest above 650 m is beginning to suffer from human encroachment, further increasing forest loss, degradation and fragmentation. Race *albiloris* occurs in several protected areas, e.g. the Northern Sierra Madre Protected Area, Quezon National Park, and the lowland forest in the Subic Bay Protected Area.

Bibliography. Bourns & Worcester (1894), Dickinson (2004), Dickinson & Kennedy (2000), Dickinson *et al.* (1991), Gilliard (1950a), Kennedy *et al.* (2000), McGregor (1909), Meinertzhagen (1923), Ogilvie-Grant (1896a), Parkes (1971), duPont & Rabor (1973a), Stattersfield *et al.* (1998).

13. Isabela Oriole

Oriolus isabellae

French: Loriot d'Isabela **German:** Isabellpirol **Spanish:** Oropéndola de Isabel
Other common names: Isabella/Green-lored/Olive-lored Oriole

Taxonomy. *Oriolus isabellae* Ogilvie-Grant, 1894, “Mountains of northern Luzon” = Isabela Province, north Luzon, Philippines.

Possibly forms a superspecies with *O. xanthonotus* and *O. steerii*, and all three were formerly placed in the alternative genus *Xanthonotus*. Sometimes considered closest to race *albiloris* of *O. steerii*. Monotypic.

Distribution. Mountains of N & W Luzon, in provinces of Bataan (probably extinct), Cagayan, Quirino and Isabela, in N Philippines.

Descriptive notes. 21–23 cm; 42–50 g. Plumage is uniformly yellowish-olive above; indistinctly brighter yellow around eye, lores yellowish-olive (as crown); upperwing yellow-olive, remiges with dull brown inner webs; tail uniform yellowish-olive above, yellower below, narrowly tipped

pale yellowish; chin, throat and underparts uniformly plain yellow; iris dark brown to reddish-brown, grey orbital ring; bill bluish-grey, paler along cutting edges; legs grey to bluish-grey or greyish-horn. Sexes alike. Immature undescribed. Voice. No information available.

Habitat. Lowland rainforest, especially thick bamboo forest, also second growth and forest edge; recorded up to 440 m. Recent recorded sites include edge of a small secondary-forest remnant near a plantation, edge of a logging road, and degraded forest with extensive bamboo stands.

Food and Feeding. Fruits; also insects and their larvae, e.g. caterpillars. Forages alone, in pairs or in small groups, from middle storey to canopy, often in fruiting trees; often joins mixed-species flocks.

Breeding. Five of six specimens from Cagayan Province had enlarged gonads in Apr; in May, three of five male specimens from Isabela Province had enlarged testes, one of five female specimens was "breeding", and one young female was being fed by an adult female. No other information.

Movements. Presumed sedentary.

Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species: present in Luzon EBA. Rare. Presumably small and rapidly declining population owing to extensive and ongoing habitat loss, degradation and fragmentation within its relatively small range of c. 90,000 km². Known from only three localities in Bataan Province and three in Cagayan Province, and one in each of Isabela and Quirino Provinces. Latest specimen records are from 1960 and 1961, when eleven collected within twelve days in 1961 near San Marino (Isabela Province), indicating that the species was reasonably common in suitable habitat at that time; rapid habitat loss since then, and the scarcity of records despite searches by increasing number of fieldworkers, imply that this species has undergone a rapid population decline. Probably extinct in SW Luzon, as no records from Bataan Province since 1947. Nevertheless, it survives in NE Luzon, as evidenced by sight records in 1993, 1994, 2003 and 2004, with one individual also captured in last-mentioned year. Loss of lowland forest assumed to be the primary threat, and by 1988 only c. 25% of Luzon's forest cover remained, most of these areas under logging concessions, and logging occurring even within reserves. Two of the historic sites are now largely deforested, and the 1993 sight record was from an isolated and degraded forest tract of only c. 100 km², probably offering no long-term prospects for the species. Several recent records, however, were from the Northern Sierra Madre Natural Park, and the species may remain within the few surviving intact forests and even use some second-growth habitats.

Bibliography. Anon. (2007g), Butchart & Stattersfield (2004), Collar (1998a), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Mallari & Tabaranza (1999), Dunning (2008), Gamauf & Tebbich (1995), Gilliard (1950a), Kennedy *et al.* (2000), van der Linde (1995), McGregor (1909), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), van Weerd & Hutchinson (2004).

14. Eurasian Golden Oriole

Oriolus oriolus

French: Loriot d'Europe

German: Pirol

Spanish: Oropéndola Europea

Other common names: (European) Golden Oriole

Taxonomy. *Coracias oriolus* Linnaeus, 1758, "in Europe and Asia" = Sweden.

Closely related to *O. kundoo* and *O. auratus*, and until recently considered to be conspecific with former; all three form a superspecies, perhaps also including *O. tenuirostris* and *O. chinensis* as members. Two proposed geographical races, *caucasicus* (from Gilan, in N Iran) and *sibiricus* (from Omsktschennaja, in Krasnoyarsk District of SC Siberia), considered inseparable from birds in rest of species' range. Monotypic.

Distribution. Breeds in W & S Europe (S from S Finland) and N Africa E to Altai Mts (S Siberia and extreme NW China) and, in S, to N Iran; non-breeding in sub-Saharan Africa.

Descriptive notes. 24–25 cm; 42–102 g. Male has head, upperparts and entire underparts rich golden-yellow; lores black; wing velvet-black.

broad yellow tips on primary coverts (forming small carpal patch on folded wing), remiges with narrow yellowish-white tips, outer primaries and outer secondaries with narrow yellowish-white edges on outer webs, when fresh; tail velvety black, central pair of feathers with narrow yellow tips, terminal third of outer feathers conspicuously golden-yellow; underwing-coverts yellow; iris red-brown to deep maroon or dark blood-red; bill dark pink; legs slaty blue. Female rather variable; commonly has head, neck, mantle and back bright greenish-yellow, rump yellower, lores golden-yellow; underparts with yellowish tips; chin to upper breast pale grey, becoming yellowish-white on belly, all streaked blackish (most heavily on chest), undertail-coverts bright yellow-green; bare parts as male, but duller; some (older) females are similar to males but duller yellow and usually with at least faint streaking on underparts. Immature is similar to female, but generally duller above and more heavily streaked below. Voice. Loud, melodious, liquid, fluty whistles, e.g. "weeka-laweela-weeo", "weelo-wallo-weelyo", "tilly-cleocleoo", "teeloo-hoh-weeyo"; also quiet antiphonal duet, whistling song of male answered by female with short song, "skweeewer", or call like that of a falcon (*Falco*). Aggressive or alarm call "skaaaa" or "kweeer".

Habitat. In W Europe, usually in semi-open, mixed broadleaf woodlands and plantations, riverine forests with tall willows (*Salix*) and poplars (*Populus*), forested steppes, groves, copses, orchards, parks, large gardens, windbreaks, avenue trees, and other tree clumps in cultivated areas, also in larger and more continuous deciduous, coniferous or mixed forests in E Europe; usually below 600 m, but up to 1300 m in Alps, 1800 m in Morocco, and 2000 m in Russia. Usually avoids treeless habitats, but forages in treeless heath and in sand dunes on almost treeless islands. In Asia, found also in floodplain woods and groves, riverine vegetation, open deciduous woods, village plantations, taiga edges and oases, to 2150 m. In African non-breeding quarters, in semi-arid to humid deciduous woodlands, e.g. miombo (*Brachystegia*) and mopane (*Colophospermum*), forest edges, tall closed-canopy gallery forest, riverine acacias (*Acacia*), forest-savanna mosaics, tree savannas, exotic plantations, windbreaks, orchards, gardens, up to 1500 m. On migration, also in

drier, more open bush and savannas, gardens, isolated fig trees (*Ficus*), and oases, to 2200 m; has been observed roosting during midday in the shade of fissures on rock faces during spring migration in N Cameroon.

Food and Feeding. Mainly small invertebrates and fruits; occasionally seeds, nectar, pollen; rarely, small lizards, small mammals, eggs and nestlings. Diet during early part of breeding season mainly invertebrates and especially their larvae, e.g. earthworms (Oligochaeta), leeches (Hirudinea), snails (Gastropoda), spiders (Araneae), damselflies and dragonflies (Odonata), crickets, katydids and grasshoppers (Orthoptera), termites (Isoptera), shield bugs (Acanthosomatidae), jewel bugs (Scutelleridae), stink bugs (Pentatomidae), cicadas (Cicadidae), beetles (Coleoptera), snakeflies (Raphidioptera), mantid flies (Mantispidae), caddis flies (Trichoptera), gadflies (Tabanidae), hoverflies (Syrphidae), crane flies (Tipulidae), Hymenoptera (sawflies, wasps, hornets, bumblebees, bees, ants), moths and butterflies (Lepidoptera, especially their caterpillars); during later part of breeding season (when young 8–10 days old), during migration and on wintering grounds consumes more fruits and berries (diet in Kenya 75% fruits), e.g. bilberries (*Vaccinium*), blackberries (*Rubus*), elderberries (*Sambucus*), mulberries (*Morus*), raspberries (*Rubus idaeus*), strawberries (*Fragaria*), blackcurrants (*Ribes nigrum*), redcurrants (*Ribes rubrum*), cherries (*Prunus*), dates, figs, grapes (*Vitis*), loquats (*Eriobotrya japonica*), olives (*Olea*), peaches, pears, plums, European yew (*Taxus baccata*), rowan (*Sorbus aucuparia*), wild service tree (*Sorbus terminalis*), Transvaal saffronwood (*Cassine transvaalensis*) and exotic neem (*Azadirachta indica*). Rarely, takes barley, oats, seeds, oak (*Quercus*) flowers, flowering shoots, leaf buds, pollen, nectar; rarely, also lizards e.g. *Lacerta vivipara*, small mammals e.g. *Apodemus* mouse that had been speared by Red-backed Shrike (*Lanius collurio*), and bird eggs and nestlings. Forages alone or in pairs, also in small groups after breeding season; sometimes joins mixed-species flocks during non-breeding season. Mainly in canopy, sometimes in small to large groups in fruiting trees, especially figs. Sometimes flycatches insects (e.g. flying termites) in air or forages on ground (e.g. for earthworms, caterpillars, beetles); may hover briefly before dropping to ground in manner of kestrel (*Falco*), especially in treeless areas. Hairy caterpillars vigorously shaken and beaten against vegetation to remove hairs before consumption.

Breeding. Egg-laying mainly in May–Jun, sometimes early Jul. After arriving on territory, male starts singing and chases away intruders, including conspecifics and potential mammalian and avian predators; female arrives later, and courtship displays involve vigorous chases and vocal duets. Nest built exclusively (or almost exclusively) by female in 6–15 days (exceptionally 28 days), although male may collect some material; a shallow to deep open-cup structure woven from grass, sedges, reeds, leaves, twigs, cloth, string, paper and plastic strips, strips of bark and other plant fibres, lined with fine fibres, roots and grasses, feathers, cocoons, cobweb, down, cotton, fur, wool, moss, lichens, straw and small pieces of paper, external diameter 8–20 cm, height 6–15 cm, internal diameter 7–13 cm, depth 3–13 cm, thickness 1–5 cm, dry weight 20–30 g; suspended hammock-like in thin, horizontal forked branch (diameter 0.6–2.5 cm) usually high in outer edge of well-foliaged tree canopy (rarely, wedged in between trunk and a branch) and often near but rarely over water. Clutch 2–6 eggs, usually 3–5, white, pinkish-white or creamy with brownish-grey or purplish-black spots and streaks, these sometimes concentrated at obtuse end, size 26.5–36 × 19.4–23.5 mm; replacement laid only after early loss; incubation by both sexes, mostly by female, period 13–20 days, mostly 16–17 days; chicks hatch within 2–3 days of each other, brooded almost exclusively by female, but fed by both sexes (mostly with invertebrates of increasing size as young grow, later also with berries and fruits), nestling period 13–20 days, generally 16–17 days; fledglings may be accompanied and fed by parents until Aug–Sept, just prior to migration. One record of nest being parasitized by Common Cuckoo (*Cuculus canorus*). Age of first breeding 2–3 years.

Movements. Migratory. Migrates mostly at night, but spring passage also during day. In autumn (Jul–Sept) all populations head towards E Mediterranean (where often gorge on fruits), and from then until Dec move S through E Africa towards main wintering areas in Cameroon and Central African Republic, and all moist deciduous woodlands S of 5° S, where present Oct–Apr; individuals often return to same locality year after year. Spring migration, beginning in Feb, is faster and more direct, many individuals crossing Sahara as far W as E Morocco, reaching Palearctic breeding grounds in Apr–May; older males arrive in Europe c. 2–10 days (exceptionally 20 days) before females and young males. Recorded as autumn vagrant in NW Afghanistan, Ladakh, coastal Pakistan and Sri Lanka. Sight records from Maldives and Andamans may refer either to present species or to *O. kundoo*.

Status and Conservation. Not globally threatened. Estimated European population of 6,700,000–14,000,000 individuals and a large range of c. 10,000,000 km² make this a species of least conservation concern. N limit of range has moved slowly N, e.g. first breeding observed in Denmark in middle of 19th century, in Sweden in 1932, in UK in 1960s, and in Norway in 1972, possibly a result of increase in temperatures. Occurs in many protected areas throughout breeding and non-breeding ranges. In non-breeding quarters average 0.1 individuals/ha in Tsavo East National Park, in Kenya, with up to 0.7 individuals/ha in riverine forests, but average of only 0.001 individuals/ha in deciduous broadleaf woodlands in Zimbabwe. Can cause some damage in commercial fruit orchards; in particular, autumn migrants gathering in E Mediterranean considered a pest by some fruit-farmers, as they consume large quantities of fruit.

Bibliography. Archer & Godman (1961), Bannerman (1953), Baumann (1999a, 1999b, 2000, 2001), Bezzel (1989), Brooke (1970a), Burfield & van Bommel (2004), Cooper (1969), Cramp & Perrins (1993), Creutz (1988), Dementiev *et al.* (1954a, 1970), Dunning (2008), Durango (1955), Feige (1986, 1995), Frandsen (1982), Fry *et al.* (2000), Ginn *et al.* (1989), Goodman & Meininger (1989), Haffer (1993g), Harrison *et al.* (1997), Hartert (1903a), Hockey, Dean & Ryan (2005), Hockey, Underhill *et al.* (1989), King (1984b), Lack (1985), Mackworth-Praed & Grant (1960, 1963), Martin & Tyler (1966), Mason (2004), Meinertzhagen (1923, 1954), Melnikov (1998), Meyer de Schauensee (1984), Milwright (1988), Paz (1987), Plucinski (1982), Prokop (1982), Rasmussen & Anderton (2005b), Rauls (1953), Reade & Hosking (1967), Reinhardt (1986), Reinsch (1959a, 1959b, 1961), Reinsch & Warnecke (1971), Robertson (1980), Rogacheva (1992), Schneller (1980), Schönwetter & Meise (1983), Skinner (1985), Stark (1900), Stuart Baker (1926), Thévenot *et al.* (2003), Uhlenhaut (1999), Vaurie (1958, 1959), Voous (1960), Wassmann (1986a, 1986b, 1993, 1997a, 1997b, 2004), Wassmann & Böhm (1995a, 1995b), Zimmerman *et al.* (1996), Zippelius (1972).

15. Indian Golden Oriole

Oriolus kundoo

French: Loriot indien

German: Indienpirol

Spanish: Oropéndola India

Taxonomy. *Oriolus Kundoo* Sykes, 1832, Dukhun (= Deccan), India.

Closely related to *O. oriolus* and *O. auratus*; until recently considered to be conspecific with former, but differs in morphology and vocalizations and the two appear not to intergrade; all three form a superspecies, perhaps also including *O. tenuirostris* and *O. chinensis* as members. Three proposed geographical forms, *yarkandensis* (from Yarkand, in E Turkestan), *turkestanica* (Turkestan City) and *baltistanicus* (Dagoni, in Baltistan), are considered untenable. Monotypic.

Distribution. Breeds Uzbekistan, E Turkmenistan, SE Kazakhstan, Kyrgyzstan, Tajikistan, extreme W China (Tien Shan), Baluchistan hills and from N & E Afghanistan E in Himalayas to Nepal, and S through most of peninsular India; non-breeding also farther S in India and in Sri Lanka.

Descriptive notes. 24–25 cm; 60–95 g. Male has head, upperparts and entire underparts rich golden-yellow, black of lores extending as narrow black streak around and behind eye; upperwing velvety black, with broad yellow tips to primary coverts forming large yellow carpal patch on folded wing, remiges with yellowish-white tips, outer primaries and outer secondaries with narrow yellowish-white edges on outer webs (those of secondaries sometimes well marked), outermost tertial tipped yellowish-white; tail velvety black, central pair of feathers with narrow yellow tips, terminal two-thirds of outer feathers conspicu-

ously golden-yellow; underwing-coverts yellow; iris red; bill dark pink; legs slaty blue. Distinguished from *O. oriolus* mainly by black eye patch, much more yellow in wing, including larger yellow carpal patch, and longer bill. Female variable; commonly has head, neck, mantle and back bright yellowish-green, rump yellow; lores dark, wing green or brownish, tail olive, outer rectrices with yellowish tips; chin to upper breast pale grey, becoming yellowish-white on belly, all streaked blackish (streaking heaviest on chest), undertail-coverts bright yellow-green; bare parts as male but duller; sometimes more similar to male. Juvenile has bright golden-yellow face and upperparts, yellowish supercilium, usually hint of long dark eye patch, outer rectrices extensively (more than a third) tipped yellow, very heavy black streaking below, bill black; first-year male as female, but often with mix of adult and immature characters. **Voice.** Song a flute melodious “pee-lo” or “pee-lo-lo”, “who-he-heer” or “weela whee-oh”, generally similar to that of *O. oriolus* but more complex, with shorter, mellower strophes and narrower range of pitch; may give a sweet, prolonged subsong. Calls most commonly a harsh “chee-ah” or “kaach”; also a nasal hiss “ka-a-lee-aa” or a very loud, nasal, upslurred miaowing that begins clearly but ends in harsh screeching sound; sometimes a rapid “tur-tur-tur-tur”.

Habitat. Open deciduous and semi-evergreen forests, forest edge, woodland, thorny forest, thickets, poplar (*Populus*) plantations, avenue trees, mangoes (*Mangifera*), orchards, village groves, parks, gardens, and fairly open country with scattered trees, e.g. riverine vegetation; to 4400 m in Himalayas, but usually below 1800 m.

Food and Feeding. Berries, e.g. of *Lantana*, and fruits, e.g. cherries (*Prunus*), mulberries (*Morus alba*), silk-cotton tree (*Bombax malabarica*), neem (*Azadirachta indica*), and figs (*Ficus*), but especially mangoes; also buds, nectar, e.g. of *Salmalia malabarica* and *Erythrina indica*. Also invertebrates, e.g. spiders (Araneae), praying mantises (Mantodea), flies (Diptera), beetles (Coleoptera), tree grasshoppers (Orthoptera), cicadas and cicada eggs (Cicadidae), other bugs (Hemiptera), ants (Formicidae), and especially caterpillars. Once seen with flying lizard (*Draco*). Forages alone, in pairs and sometimes in small groups; sometimes joins mixed-species flocks. Mostly in dense canopy of trees; may drop to ground to catch insects.

Breeding. Breeds in Jun in Afghanistan, May–Jun in Nepal and Apr–Sept in India. Male calls constantly on territory during breeding season; female arrives a few days later, and courtship displays involve vigorous chases. Nest built exclusively (or almost exclusively) by female, male may collect some material; a moderately deep open cup woven from fine grass stems, leaves, hemp stems, fine roots, seed down, slender strips of bark and sometimes other materials (e.g. snakeskin, hair, feathers, cotton, wool, fur, strips of paper, cloth, thread and string, and other vegetable fibres), lined with fine grass, vegetable down, hair and feathers, bound with small amounts of spider web, often draped on outside with cobwebs, bits of papery bark, rags and other rubbish, external diameter 12.2–13 cm, internal diameter 6.4–9.1 cm, internal depth 3.8–7.6 cm, thickness 2–3 cm; suspended hammock-like in thin, horizontal forked branch at variable height, usually high in outer edge of well-foliaged tree canopy (but sometimes as low as 3 m), and usually near and sometimes above water, e.g. in willow (*Salix*) surrounded by water; often close to nest of aggressive Hair-crested Drongo (*Dicrurus hottentottus*) or Black Drongo (*Dicrurus macrocerus*). Clutch 1–5 eggs, usually 2–4, white, with a few pale yellowish-brown, deep purplish-brown, deep reddish-brown or blackish spots (sometimes with brownish-pink haloes) concentrated at obtuse end, dimensions 25–34 × 19–22.3 mm; incubation by female, male sometimes helping a little, period 14–15 days; chicks brooded exclusively (or almost exclusively) by female, fed by both sexes (first with tiny insects and caterpillars, later with much larger invertebrates), nestling period 14–15 days; young stay with parents for c. 1 month after fledging. One record of adult feeding a fledgling cuckoo (of genus *Cuculus*).

Movements. Resident in C and parts of N India, with local movements depending on fruit availability. Breeding summer visitor in C Asia, Afghanistan and N Indian Subcontinent; in N India, arrival Apr–May (when mangoes ripen) and departure Aug–Sept; present late Mar to Aug in W & N Pakistan and Mar–Nov in Nepal. Winter visitor in S India as far S as Cape Comorin and in Sri Lanka (Dec–Mar). Males usually arrive back on breeding territories a few days before females. Sight records from Maldives and Andamans may refer either to present species or to *O. oriolus*.

Status and Conservation. Not globally threatened. Fairly common to locally common. Occurs over large range, which includes various protected areas.

Bibliography. Ali & Ripley (1972a), Bates & Lowther (1952), Chen Fuguan *et al.* (1998), Cramp & Perrins (1993), Dementiev *et al.* (1954a, 1970), Dharmakumarsinhji (1954), Feige (1995), Fleming *et al.* (1976, 1984), Grewal (1993), Grimmett *et al.* (1998), Hartert (1903a), Henry (1998), Hume & Oates (1889), Inskipp & Inskipp (1991), Lowther (1949), Meinertzhagen (1923), Rasmussen & Anderton (2005b), Ripley (1982), Roberts (1992), Schönwetter & Meise (1983), Stuart Baker (1926), Vaurie (1958, 1959), Whistler & Kinnear (1949), Yahya (1981).

16. African Golden Oriole

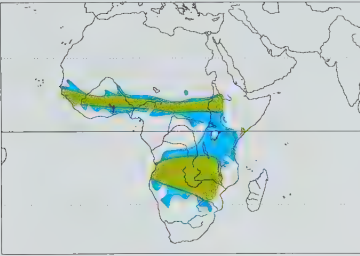

Oriolus auratus

French: Lorient doré **German:** Schwarzzihrpirol **Spanish:** Oropéndola Africana
Other common names: African Oriole

Taxonomy. *Oriolus auratus* Vieillot, 1817, Africa = Ghana. Closely related to *O. oriolus* and *O. kundoo*, with which it forms a superspecies, perhaps including also *O. tenuirostris* and *O. chinensis* as members. Two subspecies recognized.

Subspecies and Distribution.
O. a. auratus Vieillot, 1817 – breeds in N African tropics in broadleaf savanna woodland from Senegambia E to Sudan and W Ethiopia, and in S Somalia; seasonal movements N & S of breeding range include N Uganda and W Kenya.

O. a. notatus W. K. H. Peters, 1868 – breeds S African tropics in broadleaf savanna woodland from Angola E to C Mozambique; seasonal movements N & S of breeding range include E Africa and coastal islands.

Descriptive notes. 20 cm; 60–80 g. Male nominate race is bright golden-yellow above and below, except for black on lores and extending backwards as black stripe through eye above ear-coverts and narrowing onto side of nape; upperwing black, primaries and outer secondaries with pale yellow tips and narrow whitish edging, inner secondaries, tertials and greater coverts with broader yellow edges and tips, primary coverts narrowly tipped yellow, other upperwing-coverts also yellow; central pair of tail feathers blackish with yellow tips, remaining rectrices almost entirely yellow; underwing silvery grey; iris red; bill brownish-

pink, brownish-red or red; legs bluish-grey. Female is greenish-yellow above, dull yellow faintly streaked olive below; lores and area around eye dusky olive, wing brownish-black, primaries narrowly edged whitish, secondaries and tertials washed with olive and more broadly tipped and edged yellow, primary coverts with yellow edges and tips, tail dark olive or brown with yellow tips on all feathers except central pair; chin to breast whitish to pale yellow with grey streaks, belly pale yellow with darker streaks, streaking fainter on lower belly, undertail-coverts bright yellow; bare parts as male. Immature is like female, but yellower olive above and less streaked below. Race *notatus* male has broader yellow edges and tips on secondaries, tertials and primary coverts, so that the closed wing looks even yellower than that of nominate. **Voice.** Song “weelo-tyoo-tyoo-wo” or “weelo-lo-weeluweeyu”; in display higher-pitched phrases and a long-drawn “du-wee-weeeyr”.

Aggression or alarm call a harsh “rrraaaaah” or mewing “myaaaceeh”. Vocalizations very similar to those of *O. oriolus*. Once recorded mimicking call of Black-crowned Tchagra (*Tchagra senegalus*).

Habitat. Tall mesic broadleaf deciduous savanna woodlands, especially miombo (*Brachystegia*, *gusu* (*Baikiaea*) and mopane (*Colophospermum*), also dense closed-canopy broadleaf *Burkea africana* woodland, thick bushes around rocky hills, semi-evergreen gallery forest along major rivers; also swamp-fringing woodlands bordering the Okavango in N Botswana. Sometimes uses evergreen forest, forest edge, well-timbered farmland and gardens, and more arid thorn-scrub savanna. Sea-level to 2300 m.

Food and Feeding. Fruits and berries, e.g. of mulberries (*Morus*), neem (*Azadirachta indica*), *Euclea*, figs (*Ficus*); also various invertebrates, e.g. insect eggs and larvae, beetles (Coleoptera), flies (Diptera), ants (Formicidae), termites (Isoptera), locusts (Acrididae), and caterpillars; nectar taken rarely. Forages alone, in pairs or in small groups; often joins mixed-species flocks. Mostly in dense canopy, but sometimes on ground; sometimes in small groups in fruiting trees. Invertebrate items gleaned from substrate, and some (e.g. flying ants or termites) caught by aerial flycatching. Caterpillars habitually beaten against branches before being consumed.

Breeding. In N of range (nominate race) season Jul–Aug in Senegal, Apr–Jul in Gambia, Mar–Nov in Mali, May–Aug in Togo and Mar–Apr in Nigeria; in S (*notatus*) Aug–Nov in Angola, Dec–Apr in DR Congo, Sept–Nov in Zambia, Oct–Dec in Malawi, Mar–May in Botswana, Aug–Jan in Zimbabwe and Sept–Jan in Mozambique. Deep, fairly thin-walled open cup-nest woven from dry grasses, stems, leaves, rootlets, tendrils, *Usnea* lichens, woolly plant down and strands of pliable inner bark, with small amounts of spider web used for binding, internal diameter 8–10 cm, depth 5–5.8 cm, thickness 7.5 cm, suspended hammock-like in horizontal fork of thin branch usually high in well-foliaged tree canopy, typically *Brachystegia* but also alien such as eucalypt (*Eucalyptus*), usually close to centre of tree. Clutch 1–5 eggs, usually 2–3, buffy pink or creamy white, with blackish-brown, reddish-brown and purplish-grey spots and streaks with deep rose-coloured haloes concentrated at obtuse end, dimensions 26–33.3 × 19.2–21.8 mm; incubation period 16–17 days; chicks brooded mainly or entirely by female, but fed by both sexes (mostly with invertebrates, e.g. caterpillars), nestling period c. 15 days. Nests parasitized rarely by cuckoos (Cuculidae). Average breeding success in Zimbabwe study 0.4 fledglings per nesting attempt.

Movements. Intra-African migrant, with post-breeding movements into more arid habitats both farther N & S of breeding ranges of both races; movements not well understood, and populations in some areas resident or only partially migratory. Heavy deposits of fat in neck and abdomen of two specimens may indicate fat deposition in preparation for long-distance migration.

Status and Conservation. Not globally threatened. Common in parts of its range, which covers c. 5,000,000 km². Average density in seven woodland types in N Botswana 0.09 individuals/ha. Increasing loss, degradation and fragmentation of suitable woodlands is of some concern, as illustrated by e.g. loss of miombo woodlands in Zimbabwe, and has led to some population decreases, but not sufficient to require conservation action. Occurs in various protected areas, e.g. Boucle du Baoulé Reserve, in Mali, Comoé National Park, in Ivory Coast, Kalamaloué National Park, in Cameroon, Quicama National Park, in Angola, Dzalanyama Reserve, in Malawi, and Gorongosa National Park, in Mozambique.

Bibliography. Ash & Miskell (1998), Bannerman (1939), Baumann (2001), Borrett (1972), Borrow & Demy (2001), Brooke (1965, 1970a, 1986), Chapin (1954), Dowsett *et al.* (2008), Dowsett-Lemaire (1989b), Dowsett-Lemaire & Dowsett (2006), Fry *et al.* (2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey *et al.* (2005), Irwin (1981b), Mackworth-Præd & Grant (1960), Marshall (1959), Meinertzhagen (1923), Nikolaus (1987), Oatley (1969), Payne & Payne (1967), Pettet (1977), Riddell (2000), Schönwetter & Meise (1983), Short & Horne (2006), Sinclair *et al.* (2002), Skinner (1989, 1995), Tarboton (2001), Vincent (1936).

17. Slender-billed Oriole

Oriolus tenuirostris

French: Lorient à bec effilé **German:** Dünnschnabelpirol **Spanish:** Oropéndola Picofina
Other common names: Slender-billed Black-naped Oriole

Taxonomy. *Oriolus tenuirostris* Blyth, 1846, central India; error = Assam. Closely related to and sometimes treated as conspecific with *O. chinensis*, the two forming a superspecies; alternatively, both sometimes considered to belong to the superspecies formed by *O. oriolus*, *O. kundoo* and *O. auratus*. Race *invisus* regarded by some authors as being of doubtful validity. Ranges listed are tentative, as status in many areas poorly known, partly because of taxonomic uncertainties (and confusion with *O. chinensis*). Two subspecies currently recognized.

Subspecies and Distribution.
O. t. tenuirostris Blyth, 1846 – breeds Bhutan and NE India E to S China (SW Yunnan), Myanmar, Laos, NC Thailand and N & C Vietnam; non-breeding also W to E Nepal and S to S Myanmar and W Thailand.
O. t. invisus Riley, 1940 – S Vietnam (S Annam).

Descriptive notes. 21–25 cm; 72–92 g. Male nominate race has head golden-yellow apart from broad black band extending from lores around eye and across back of head; mantle and back golden-olive, rump duller; remiges black, outer primaries tipped yellowish-white and narrowly edged white, inner primaries, secondaries and tertials broadly edged golden-olive and tipped bright yellow, upperwing-coverts golden-olive; tail has outermost rectrices mostly yellow and inner pair black, the intervening feathers with amount of yellow decreasing towards inner pair; throat and underparts entirely golden-yellow; iris red; bill

livid pink; legs slaty blue. Distinguished from very similar *O. chinensis* mainly by much narrower black band on nape, duller (not golden-yellow) mantle and back (but similar in colour to female of *O. chinensis*), and longer, more decurved and more slender bill. Female is very similar to male but slightly darker above, dark colour sometimes extending onto crown and obscuring nuchal band, rump olive; yellow underparts have narrow dark streaks. Immature is yellowish-green above, creamy white on chest to yellowish on belly, entire underside heavily streaked black; bill black. Race *invisus* is smaller than nominate, inner secondaries with larger yellow tips. **VOICE.** Song a variety of mellow fluty “wheow” notes usually preceded by 2 or 3 short high “kick” notes (like those of a *Dendrocopos* woodpecker), alternatively as “chuck, tarry-you”. Calls include a rather harsh mewling note, also short nasal notes and harsh snarling sounds.

Habitat. Montane forests, e.g. open pine (*Pinus*) forest, mixed pine-oak (*Pinus-Quercus*) forest, dry open semi-evergreen or broadleaf evergreen forests, also forest edge, bamboo, plantations, gardens, groves, tea-shaded trees, clearings and open country with scattered tree clumps; up to 1500 m in Thailand, but to 2100 m in India and Bhutan, and at 2500–4300 m in China. In non-breeding season found down to 600 m in open evergreen broadleaf forests and secondary growth.

Food and Feeding. Fruits, e.g. figs (*Ficus*) and *Trema orientalis*, also nectar, e.g. of *Salmalia* and *Erythrina*; also insects. Forages alone or in pairs high up in trees; rarely, descends to ground to take caterpillars.

Breeding. Season Apr/May–Jun. Nest a moderately deep open cup of grass stems, leaves, roots, seed down, slender strips of bark and other fine material, lined with fine grass, down, hair and feathers, suspended hammock-like from thin, horizontal forked branch at variable height, usually in outer edge of well-foliaged tree canopy, sometimes attached to creepers on oak, and often near nest of Black Drongo (*Dicrurus macrocerus*); nest and nest-site like those of *O. kundoo*. Clutch 2–4 eggs, very similar to those of *O. kundoo* but nearly always have a warm pink to yellowish-pink tinge with red, light chestnut, purple-brown or blackish spots, often with reddish haloes, 26.1–29.6 × 19–21.7 mm. No other information.

Movements. Generally resident, but some migratory; status in many areas poorly known, partly because of taxonomic uncertainties (formerly treated as conspecific with *O. chinensis*) and patchy records. Probably resident in Bhutan and NE India (Arunachal Pradesh, Nagaland); resident Myanmar, Laos, NW Vietnam and parts of Thailand; probably only a breeding visitor in China (Yunnan). Non-breeders occur to the W in E Nepal, Sikkim, hills of S Assam, possibly also Bihar, West Bengal and Bangladesh, and to the S in parts of Thailand and Indochina (limits uncertain).

Status and Conservation. Not globally threatened. Fairly common to common in much of range of c. 1,000,000–10,000,000 km². Almost extinct in some areas in China owing to hunting and to trapping for the cagebird trade and taxidermy. Occurs in various protected areas, e.g. Mae Wong National Park, in Thailand, and other reasonably secure sites, and thought therefore not to be at any immediate risk.

Bibliography. Ali & Ripley (1972a), Chen Fuguan *et al.* (1998), Cheng Tsohsin (1976, 1987), Dickinson (2004), Etchécopar & Hübner (1983), Grimmett *et al.* (1998), Herklots (1953), Kazmierczak (2000), King *et al.* (1975), Lekagul & Round (1991), MacKinnon & Phillips (2000), McCarthy (2006), Meyer de Schauensee (1984), Rand & Fleming (1957), Rasmussen & Anderson (2005b), Robson (2000b, 2005b), Schönwetter & Meise (1983), Smythies (1986), Stuart Baker (1926), Vaurie (1959).

18. Black-naped Oriole

Oriolus chinensis

French: Loriot de Chine **German:** Schwarzackenspirol **Spanish:** Oropéndola China
Other common names: Eastern Black-naped Oriole (*diffusus*); Andaman Black-naped Oriole (*andamanensis*); Nicobar Black-naped Oriole (*macrourus*)

Taxonomy. *Oriolus chinensis* Linnaeus, 1766, “China”; error = Manila, Philippines.

Closely related to and sometimes treated as conspecific with *O. temurostris*, the two forming a superspecies; alternatively, both sometimes considered to belong to the superspecies formed by *O. oriolus*, *O. kundoo* and *O. auras*. Geographical variation marked, and races almost certainly comprise several species; further study required. Race *diffusus* previously known by name *indicus* (based on birds from non-breeding range in SW India), but latter name invalid, as preoccupied. Other proposed races are *saani* (from Mayu I, in Moluccas), now synonymized with *formosus*, *macassariensis* (Makassar and Indragiri, in SW Sulawesi), included in *celebensis*, and *oscillans* (Tukangbesi Is, SE of Sulawesi), merged with *boneratisensis*; and, in Philippines, *palawanensis* (Puerto Princesa, on Palawan), *fugaensis* (Fuga I, off N Luzon) and *sorsogonensis* (Sorsogon, in S Luzon), all now subsumed in nominate. Twenty subspecies currently recognized.

Subspecies and Distribution.

O. c. diffusus Sharpe, 1877 – breeds SE Russia (Amurland), Korea and S throughout E half of China (E from W Sichuan and Yunnan) to Hainan, also SW Myanmar, N Laos and Taiwan; non-breeding mainly India, Bangladesh, Myanmar, Thailand and S Indochina.
O. c. andamanensis Beavan, 1867 – Andaman Is.
O. c. macrourus Blyth, 1846 – Nicobar Is.
O. c. maculatus Vieillot, 1817 – extreme S Thailand, Peninsular Malaysia, Singapore, mainland Sumatra, Bangka, Belitung, Java and Bali.
O. c. mundus Richmond, 1903 – Simelue and Nias, off W Sumatra.
O. c. richmondi Oberholser, 1912 – Siberut and Pagai Is, off W Sumatra.
O. c. sipora Chasen & Kloss, 1926 – Sipura, off W Sumatra.
O. c. lamprochryseus Oberholser, 1917 – Karamian and Masalembu Is, in E Java Sea.
O. c. insularis Vorderman, 1893 – Sapudi, Raas and Kangean Is, in Bali Sea.
O. c. chinensis Linnaeus, 1766 – N & W Philippines (Luzon, Mindoro, Palawan and surrounding smaller islands).
O. c. yamamurae Nagamichi Kuroda, 1927 – C & S Philippines (Tablas, Romblon, Sibuyan, Masbate, Panay, Samar, Negros, Cebu, Bohol, Leyte, Basilan, Mindanao and surrounding smaller islands).

O. c. suluensis Sharpe, 1877 – Sulu Archipelago (S from West Bolod and East Bolod), in SW Philippines.

O. c. melanisticus A. B. Meyer & Wilesworth, 1894 – Talaud Is (Karakelong, Salibabu, Kaburung), S of Philippines.

O. c. sangirensis A. B. Meyer & Wilesworth, 1898 – N Sangir Archipelago (Sangir I, Tabukan I), N of Sulawesi.

O. c. formosus Cabanis, 1872 – S Sangir Archipelago (islands of Sia, Tahulandang, Ruang, Biaro) and Mayu I (E of NE Sulawesi).

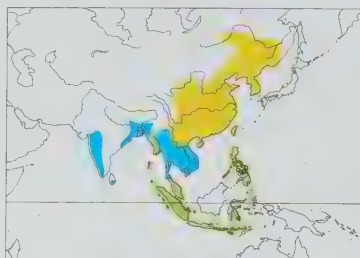

O. c. celebensis (Walden, 1872) – Sulawesi and surrounding islands (Talisei, Bangka, Lembeh, Kabaena, Muna, Butung, Tanakeke), including Togian Is.

O. c. stresemanni Neumann, 1939 – Peleng (in Banggai Archipelago).

O. c. frontalis Wallace, 1863 – Taliabu (in Sula Archipelago).

O. c. boneratisensis A. B. Meyer & Wilesworth, 1896 – islands in Flores Sea (Kayuadi, Tanahjampea, Kalao, Bonerate, Kalaotoa, Madu), and Tukangbesi Is (in W Banda Sea).

O. c. broderipii Bonaparte, 1850 – Lesser Sunda (Lombok, Sumbawa, Komodo, Rinca, Sumba, Flores, Paloe, Besar, Lomblen, Pantar, Alor).

Descriptive notes. 23–28 cm; 65–100 g. Male nominate race has head, upperparts and underparts entirely golden-yellow, apart from black on lores and in broad band through eye and across hindcrown; most of wing black, secondary coverts golden-yellow, primaries narrowly edged white, tertials tipped yellow; tail feathers black, outer pair with distal half yellow, central pair with yellow tips, other feather pairs with decreasing amount of yellow from outers inwards; iris reddish-brown or grey; bill livid pink, paler on cutting edges and tip; legs slaty blue. Female is similar to male, but mantle yellowish-olive. Immature has

upperparts yellowish-green, underparts creamy white with black streaks, undertail-coverts yellow; bill black. Races vary extensively in size and colour: *yamamurae* is like nominate but shorter-winged, and yellow tips of central tail feathers much narrower; *suluensis* has yellow on head confined to small forehead patch, mantle rather pale yellow, wing entirely black, extensive yellow on outer tail feathers; *diffusus* is like nominate, but tertials and inner secondaries entirely yellow on outer edge, yellow tips of primary coverts forming small yellow patch; *andamanensis* is much smaller, has yellow of crown extending much farther back onto nape, leaving only narrow black hindcollar; *macrourus* is slightly smaller than nominate, yellow of crown extending farther back to leave narrower hindcollar (but broader than in previous), wing feathers with narrow yellowish edging, primary coverts tipped yellow (small yellow wing spot); *maculatus* is smaller than nominate, with greater extent of yellow on crown as preceding race, but yellow upperparts tinged greenish, secondaries and tertials with broader yellow edging, yellow-tipped primary coverts form large patch; *mundus* differs from nominate in being slightly smaller and generally bright lemon-yellow; *sipora* is similar to last, but has more extensive yellow on crown, yellow primary-covert spot; *richmondi* has greater extent of yellow on hindcrown than nominate and posterior upperparts tinged olive, resembles *maculatus* but yellow of remaining upperparts more orange-tinged, wing shorter, secondaries and tertials less broadly edged yellowish; *lamprochryseus* is slightly smaller than nominate, resembles *maculatus* but less greenish above, primaries narrowly edged greyish-white, inner primaries tipped buff-white, secondaries and tertials broadly edged pale yellow, primary coverts less broadly tipped lemon-yellow; *insularis* has yellow of crown extending farther back to leave only narrow black hindcollar, yellow of upperparts and underparts suffused with orange; *melanisticus* is larger and with heavier bill than nominate, has entire crown and nape black, leaving only small area of yellow on forehead, broad yellow collar on hindneck, mantle black-mottled dark olive-green or sometimes entirely black, wing feathers all black; *sangirensis* resembles previous, but mantle dark greenish-yellow, secondaries and tertials broadly edged olive; *formosus* is very similar to last but slightly larger, with larger area of yellow on forehead; *celebensis* is smaller than nominate, has top of head entirely yellow so that black occipital band very narrow and sometimes broken on nape, mantle greenish-tinged yellow, primaries narrowly edged greyish-white, tertials broadly edged greenish-yellow; *stresemanni* is smaller and much shorter-billed than nominate, yellow on head confined to small forehead patch; *frontalis* is intermediate in size between nominate and previous, yellow on head confined to small forehead patch (as previous), mantle deeper golden-yellow, often with some orange suffusion, wing entirely black; *boneratisensis* is larger than nominate, yellow colour of crown, mantle and underparts often a pure orange; *broderipii* is same size as nominate, forehead patch small (as *frontalis*) but deep orange-yellow in colour, mantle and underparts also deep orange-yellow, primary coverts with yellow tips (forming wing spot), tertials tipped yellow. **VOICE.** Much variation, but geographical differences largely unstudied. Song a loud fluty whistle, “doo-dee-oo”, “ku-i-oo”, “kwia-lu” or descending “tu-u-liu”, last note longest, and a rich and fluty “tu-u-liu”, first note shortest and last note highest; race *andamanensis* said to give quite different “chee-e op”. Call a mewling “mee-aooww” and a loud, pleasant “pee-yaaaoooww” or “kee-aaaoooww” repeated every few seconds, often several birds calling together; scolding harsh “kyerrrr”, often repeated, and given by both sexes.

Habitat. Open primary and secondary evergreen forest, mixed broadleaf forest and deciduous forest, dryland forests, forest edge, forest groves (e.g. beach casuarinas, bamboo), plantations (e.g. coconut palm, rubber), parks, orchards, gardens, wooded suburbs; also mangroves, coastal forest and scrub, and even scattered trees in open country, along roads and in villages. Lowlands and hills, up to 1600 m in China and Thailand.

Food and Feeding. Berries and fruits, e.g. *Camposperma auriculata*, *Cinnamomum iners*, *Eugenia papillosa*, *Passiflora foetida*, *Ptychosperma macarthurii*, *Vitex pubescens*, *Macaranga*, papaya (*Carica*), mango (*Mangifera*), star-fruit (*Averrhoa carambola*), low fruiting ornamental palms, but especially figs (*Ficus*). Also insects and their larvae, e.g. alate termites (Isoptera), caterpillars, grasshoppers (Orthoptera), mantids; seen to make hole in wasp and hornet (Vespidae) nests in order to extract larvae. Observed also to take small vertebrates, including bird nestlings. Forages alone, in pairs or in small groups, usually in canopy; only rarely comes down quite low, when searching for insects and larvae. Sometimes joins mixed-species flocks in fruiting trees. Most items taken while perched, but some during hovering. Many insects are habitually wiped on branch before consumption.

Breeding. Breeds in May–Jun in N of range (SE Russia), Jun–Jul in China (May–Jul in Hongkong), Apr–Jun in Andaman Is, Dec–Jun (rarely to Sept) in Peninsular Malaysia, Mar–Aug in Sumatra, Feb–Jun (nests found also in Aug and Dec) in Java, and Feb–Jun in Philippines. During pair formation, male sings and chases after female while chasing away other males. Open cup-nest built solely by female, male sometimes collecting some material, made of leaves, grasses, strips of bark, straw, rootlets, fine banyan (*Ficus*) roots, pine (*Pinus*) needles and small twigs, bound with cobwebs, usually decorated on outside with small climbing asclepiad leaves, external diameter 10–13

cm, internal diameter 6·7–9 cm, internal depth 5 cm, suspended hammock-like in thin, horizontal forked branch, usually high up and well concealed in well-foliaged tree, and often close to nest of drongo (*Dicrurus*). Clutch 2–4 eggs, white or bluish-white to pale pink or salmon-pink, with small red, cinnamon-brown, dark chocolate-brown, purplish-brown, grey and black spots with a few grey or lavender haloes concentrated at obtuse end, dimensions 25·6–34·2 × 19·9–23·8 mm; incubation period 14 days; chicks tended by both parents, no information on duration of nestling period; both parents also tend fledglings, usually only two of which survive.

Movements. Mainland *diffusus* migratory, with N populations present on breeding grounds May–Sept, migrating S & SW to overwinter in SW India and NE Indian Subcontinent, Sri Lanka (very scarce) and much of mainland SE Asia; fairly common passage migrant N Vietnam; in Japan rare but annual spring migrant (May and early Jun, exceptionally to mid-Jul), mainly on islands in Sea of Japan, also autumn passage migrant. Nominate race a partial migrant; individual ringed on Palawan was recaptured 60 months later on Mindoro, several hundred kilometres to N. Other island populations resident. Resident also SW Myanmar, extreme S Thailand and Peninsular Malaysia S to Singapore.

Status and Conservation. Not globally threatened. Common to fairly common or frequent in various parts of its range of c. 1,000,000–10,000,000 km². Status in Borneo uncertain, and the

few records possibly involve migrants of nominate race from Philippines; two records from N Borneo (Sabah) considered likely to have involved escaped cagebirds. Is regularly sold in cagebird trade. May be a pest in some areas, where sometimes causes visible damage in commercial fruit orchards. Occurs in various protected areas throughout range, and considered not to be at any immediate risk.

19. Green-headed Oriole

Oriolus chlorocephalus

French: Lorient à tête verte **German:** Grünkopfpfirl **Spanish:** Oropéndola Cabeciverde

Taxonomy. *Oriolus chlorocephalus* Shelley, 1896, Mount Chiradzulu, south Malawi. Despite being green-headed, this species is considered to be part of the "African black-headed group" along with *O. crassirostris*, *O. brachyrhynchus*, *O. monacha*, *O. percivali*, *O. larvatus* and *O. nigripennis*. Three subspecies recognized.

Subspecies and Distribution.

O. c. amani Benson, 1946 – patchily in SE Kenya and E Tanzania.
O. c. chlorocephalus Shelley, 1896 – S Malawi and C Mozambique (Mt Chipperone).
O. c. speculifer Wolters & Clancey, 1969 – SC Mozambique (Mt Gorongosa).

Descriptive notes. 21.5–24 cm. Male nominate race has head and neck to upper breast rich olive-green, separated from olive-green upperparts by bright yellow hindneck and upper mantle; lower breast to undertail-coverts bright yellow, thighs tinged olive; upperwing dark grey, primaries and secondaries having light grey outer webs with whitish edges (forming pale panel on closed wing), primary coverts bluish-grey, secondary coverts olive-green; tail has outermost feathers almost entirely yellow, central pair olive-green, the rest with yellow tips, amount of yellow decreasing inwards; iris red; bill deep red to

red-brown; legs light or dark bluish-grey. Female differs from male only in browner bill. Immature is like adult, but olive-green less intense, narrow ring of yellow feathers around eye; has mantle, chin and throat yellow-olive, breast dull yellow, mottled with olive, upper belly bright yellow with narrow olive streaks, secondaries edged and tipped white, primary coverts with broad white tips; bill blackish. Race *amani* differs from nominate only in smaller size; *speculifer* is same size as nominate, but has white tips on four primary coverts forming conspicuous white patch on closed wing. **VOICE.** Song "ku-wee-oo", "kwee-wo", "hweet-tyoo-hweedo" or "who-jo-koyyo", each phrase accompanied by quick fanning of tail, similar to that of *O. larvatus* but more liquid and less abrupt; also a simpler "cowoyo". Calls include insistent nasal mewling, louder in middle and changing in tone, "quarreeyaaa".

Habitat. Coastal forest patches in Kenya, up to 400 m. In Tanzania, primary lowland forest, rich woodlands and secondary growth with tall emergent trees, mainly between 200 m and 1000 m, but 1000–1300 m on Mt Nilo (E Usambaras). Primary submontane and riparian evergreen forests between 1000 m and 1450 m in Malawi and in C Mozambique (Mt Chipperone); primary evergreen montane forest at 750–2000 m on Mt Gorongosa, in S Mozambique, where sometimes in adjacent secondary forest and semi-open woodland.

Food and Feeding. Fruits, also some large hard seeds, and nectar; also various invertebrates, e.g. insects and their larvae. Forages alone or in pairs, from middle storey to canopy; sometimes in small groups in fruiting trees e.g. figs (*Ficus*) or in flowering trees, especially alien silky oak (*Grevillea*), where it is often found with *O. larvatus*. Sometimes joins mixed-species flocks.

Breeding. In Malawi, pair formation in Jun, calling Aug–Feb (silent Mar–Jun), and egg-laying mainly Aug–Nov; in Tanzania, a well-grown nestling observed in Nov; in Mozambique, birds with enlarged gonads and brood patches in Oct, and breeding recorded in Nov. Nest a deep, open thick-walled cup, mostly of old-man's beard lichen (*Usnea*) where available, also other plant fibres, suspended hammock-like in thin, horizontal forked branch high in well-foliaged tree canopy; territory 13–25 ha in Malawi. Clutch 2 eggs. No other information.

Movements. Resident, but may wander locally; some records in Malawi up to 40 km from nearest known population.

Status and Conservation. Not globally threatened. Fairly common to common in parts of its range of c. 22,000 km². Occurs in various protected areas, and considered therefore not at any immediate risk. In Kenya, local and uncommon in coastal forests of Arabuko-Sokoke Forest Reserve and Diani (unprotected), and locally fairly common in Jadini Forest in the Shimba Hills National Park. In Tanzania, common in Usambara Mts, and very common at Amani Nature Reserve. In Mozambique, common on Mt Gorongosa, with no evident change in numbers in recent times; incorporation of Mt Gorongosa into the adjoining Gorongosa National Park has been proposed. Less common in Malawi, where occurs at only four or five small localities, with estimated total of 55–60 pairs in 1983; continuing deforestation of remaining localities threatens the species' survival in this country.

Bibliography. Benson & Benson (1947), Britton (1977), Clancey (1985, 1996), Dowsett-Lemaire (1989b), Dowsett-Lemaire & Dowsett (2006), Fry *et al.* (2000), Ginn *et al.* (1989), Hall & Moreau (1970), Hockey *et al.* (2005), Mackworth-Præd & Grant (1960), Meinertzhagen (1923), Parker (2005), Tarboton (2001), Vincent (1936), Wolters & Clancey (1969), Zimmerman *et al.* (1996).

20. Sao Tome Oriole

Oriolus crassirostris

French: Lorient de Sao Tomé **German:** Sao-Tomé-Pfirl **Spanish:** Oropéndola de Santo Tomé

Taxonomy. *Oriolus crassirostris* Hartlaub, 1857, São Tomé.

A member of the "African black-headed group", which also includes *O. chlorocephalus*, *O. brachyrhynchus*, *O. monacha*, *O. percivali*, *O. larvatus* and *O. nigripennis*. Monotypic.

Distribution. São Tomé I, in Gulf of Guinea.

Descriptive notes. 23–24 cm; 50 g. A "washed-out" version of mainland orioles, and with more robust bill. Male has head and neck to upper breast black, throat freckled with white; mantle pale yellow, broadly streaked olive-grey, back greyish olive-green, rump paler with whitish patch at side; primaries narrowly edged white and with broad white crescent at tips, outer webs of secondaries blue-grey with white edges and tips, tertials grey-green, primary coverts black with white tips (forming conspicuous white patch on closed wing); upertail has central feathers dark olive, others black with long yellow tips, amount of yellow increasing towards outer feathers, underside of tail bright

long, mellow downslurred "tyeeow", "way-when-ya", "chip-aw-hah-aw" or "hik-kuway-kuwow" or an ascending "ko-ku-waayoo"; slower and deeper than those of other African orioles, richer and mellower than songs of other members of "African black-headed group". Scolding call a high-pitched, harsh "keea", shorter than equivalent calls of congeners.

Habitat. Inhabits primary forest up to 1600 m, also mature secondary forest and forest edge; sometimes in dry forest in N. Generally absent from cocoa plantations and from vicinity of human habitations.

Food and Feeding. Fruits, seeds; also invertebrates, e.g. hemipteran bugs, larval and adult beetles (Coleoptera). Forages alone or in pairs, from middle storey to canopy; sometimes joins mixed-species flocks.

Breeding. Breeds at least Aug–Jan, possibly as early as Jun and as late as Feb, as young observed in early Jul and Feb and juveniles during Jul–Aug and Dec–Mar, also a male with well-developed gonads in Feb. One nest, built by one individual in Sept, an open cup suspended hammock-like between two horizontal branches at height of 9 m; another was made out of leaves and shredded vegetation, and suspended between two twigs near leafy end of branch 11 m above ground. No other information.

Movements. Resident; may wander locally.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in São Tomé EBA. Locally common in primary forest. Total population thought to be fewer than 1000 individuals, confined to c. 480 km² of suitable primary and mature secondary forest habitat. Recent surveys suggest it may occur at higher densities than previously believed, i.e. 0.2–0.7 birds/ha in central montane and high-altitude mist forests, and 3–2 birds/ha in remaining areas of lowland forest in SW. Historically, large areas of forest were cleared for cocoa and coffee plantations, and intact forest remains mostly at higher elevations. Before independence of São Tomé, in 1975, plantations were frequently sprayed with pesticides, causing apparently drastic decrease in oriole numbers. Since then, many plantations have reverted to secondary growth, but recent land privatization and reintensification of agriculture may have led to increase in number of small farms, pesticide use and clearance of trees, while road developments along E & W coasts are facilitating access to previously remote areas. Protection of primary forest as a *zona ecológica* and a national park has been proposed, while a new law providing for the listing of protected areas and the protection of threatened species awaits final ratification. Improved knowledge of the species' numbers and habitat requirements may result in its population estimate being revised upwards and its threatened status being reviewed.

Bibliography. Anon. (2007g), Atkinson *et al.* (1991), Bannerman (1915a, 1939), Borrow & Deme (2001), Butchart & Stattersfield (2004), Christy & Clarke (1998), Collar, Crosby & Stattersfield (1994), Fry *et al.* (2000), Hall & Moreau (1970), Jones & Tye (2006), Meinertzhagen (1923), de Naurais (1984), Peet & Atkinson (1994), Sargeant (1994), Snow (1950), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

21. Western Black-headed Oriole

Oriolus brachyrhynchus

French: Lorient à tête noire **German:** Blauflügelpfirl **Spanish:** Oropéndola Cabecinegra
Other common names: Greenish-backed/West African Black-headed Oriole

Taxonomy. *Oriolus brachyrhynchus* Swainson, 1837, Sierra Leone.

Closely related to and perhaps forming a superspecies with *O. monacha*; the two belong to the "African black-headed group", which also includes *O. chlorocephalus*, *O. crassirostris*, *O. percivali*, *O. larvatus* and *O. nigripennis*. Two subspecies recognized.

Subspecies and Distribution.

O. b. brachyrhynchus Swainson, 1837 – rainforests in E Guinea-Bissau, SW Guinea, Sierra Leone, Liberia, Ivory Coast, Ghana, Togo and SW Benin.

O. b. laetior Sharpe, 1897 – rainforests in S Nigeria and Cameroon E to Central African Republic, extreme SW Sudan, W, C & S Uganda (and patchily in E), extreme W Kenya and extreme NW Tanzania, S to Gabon, N Angola and SW, SC & E DR Congo.

Descriptive notes. 21 cm; 42–57 g. Male nominate race has head and neck to upper breast glossy black, hindneck and uppermost mantle yellowish, rest of upperparts uniform bright yellowish olive-green; primaries and outer secondaries blackish with narrow whitish edges and tips, inner secondaries olive on outer web, edged and tipped grey (forming extensive pale grey wingpanel), tertials and upperwing-coverts yellowish-olive, outer greater coverts grey, primary coverts black with white tips (forming conspicuous white patch on closed wing); tail feathers black with olive bases and yellow tips, with progressively less olive at base and more yellow at tip from inner feathers to outer ones, underside of tail yellow and dull black; black of upper breast merges into dusky yellow on lower breast, bright yellow on belly and flanks; iris dark carmine-red; bill red-brown or pinkish-brown; legs blue-grey or dark grey. Female differs from male only on having iris chestnut-brown (not red). Immature is like adult, but head

dark olive (yellower on lores and around eye), grading into yellower olive of mantle; chin and throat olive-green, streaked yellow, breast and flanks mottled olive-yellow, belly clear yellow; upper mandible purplish, lower mandible pinkish-yellow at base and dark at tip, iris brown, legs grey-blue, grey-green or light blue. Race *laetior* differs from nominate in having distinct hindcollar brighter yellow, and lower breast bright yellow (not dusky yellow) and strongly demarcated from black of upper breast. **Voice.** Song repertoire of nominate race extensive (more than 50 variations recorded), e.g. a rich, mellow, fluty “waw-hah” (second note higher) and a shorter “waw-chop”, also “waw-kwee-hoo”, “hee-ku-waw”, “hip-oo-hooah” (last note upslurred) and rapid “tututu-weeah”; similar to song of *O. nigripennis* but rather deeper, notes more clearly separated, and changing in frequency more slowly. Scolding call a nasal “jewi-jaaa”. Race *laetior* has very varied repertoire, including mellow fluty whistle, “hoyo” or “oriole”, a similar “hohohoyee” (4 notes), “hohohoick” (3 notes) or “hohoyee” (3 notes), and other variations of this, as well as 4 or 5 rapidly repeated guttural “churk” notes, and a penetrating rasping and twanging double cry, “pisk-peisk”, with first note short, second drawn out.

Habitat. Primary forest and mature secondary forest, forest edge, treefall gaps, clearings with shrubs and tall trees, gallery forest, savanna woodlands, mature plantations and dense bushes; to 1800 m.

Food and Feeding. Invertebrates, especially caterpillars, also e.g. beetles (Coleoptera), spiders (Araneae), bugs (Hemiptera), large orthopterans; also large hard seeds and soft fruits, e.g. *Allophylus*, *Croton*, *Ficus*, *Macaranga*, *Tetrachidium didymostemon*. Forages alone, in pairs or in family groups, from middle storey to canopy, sometimes lower in treefall gaps and along logging roads. Often joins mixed-species flocks. Searches for insects in epiphytes and foliage, also on small branches; sometimes flycatches insects, e.g. winged ants (Formicidae), and observed even to feed on hornet (Vespidae) nest.

Breeding. Displays in Dec and Mar, developed gonads Aug–Dec and Mar, copulation seen in Oct, nest-building in Mar, May–Jun and Nov, and nesting in Apr–May in Liberia; pair displaying in Nov and collecting nest material in Apr in Ivory Coast; birds with enlarged gonads in Apr in Ghana; juvenile in Mar in Nigeria and adult feeding juvenile in May in Cameroon; singing and territorial pursuits most intense in Sept–Feb, birds in breeding condition Jun–Aug and Dec, adult feeding young Nov and occupied nest in Dec in Gabon; birds with developed gonads in Jan–Jul and Oct–Nov, breeding in Mar, young just out of nest in Dec, and immatures seen in Jan and Nov in DR Congo; in breeding condition Apr in Uganda and egg-laying Aug in Kenya. Deep open cup-nests woven mostly from dry vegetable matter, with *Usnea* lichen and mosses worked into outside of nest, sometimes bound with small amounts of spider web, suspended hammock-like in thin, horizontal forked branch, usually in well-foliaged tree canopy. Clutch 2 eggs; incubation by female, fed on nest by male. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Fairly common to common and widespread in its range of c. 2,300,000 km². Estimated densities 0.08–0.15 pairs/ha in high forest in Ghana, 0.10–0.12 pairs/ha in primary forest and 0.06–0.08 pairs/ha in old secondary forest in Gabon (M’Passa), and 0.08–0.15 pairs/ha in high forest in Liberia. Occurs in various protected areas, e.g. Bia National Park, in Ghana, Odzala and Nouabalé-Ndoki National Parks, in PR Congo, and Bwindi-Impenetrable Forest National Park, Mount Elgon National Park and Malabigambo and Mount Moroto Forest Reserves, in Uganda.

Bibliography. Bannerman (1939), Borrow & Demey (2001), Chapin (1954), Dean (2000), Dowsett-Lemaire (1996), Fry *et al.* (2000), Gatter (1997), Grimes (1987), Gyldestolpe (1924), Hall & Moreau (1970), Happel (1986), Hillman & Hillman (1986), Mackworth-Præd & Grant (1960, 1973), Mann (1985), Marchant (1951), Marshall (1959), Nikolaus (1987), Rand (1959), Rodewald *et al.* (1994), Sinclair & Ryan (2003).

22. Ethiopian Black-headed Oriole
Oriolus monacha

French: Lorient moine **German:** Mönchspirol **Spanish:** Oropéndola Monje
Other common names: Dark-headed/(Black-headed) Forest Oriole, Abyssinian Oriole

Taxonomy. *Turdus monacha* J. F. Gmelin, 1789, “Abyssinia” = Eritrea. Closely related to and perhaps forming a superspecies with *O. brachyrhynchus*; the two belong to the “African black-headed group”, which also includes *O. chlorocephalus*, *O. crassirostris*, *O. percivali*, *O. larvatus* and *O. nigripennis*. The name *permistus* is considered to be a younger synonym of *menelikii*. Races intergrade in C Ethiopia. Two subspecies recognized.

Subspecies and Distribution.

O. m. monacha (J. F. Gmelin, 1789) – Eritrea and N Ethiopia.

O. m. menelikii Blundell & Lovat, 1899 – S Ethiopia.

Descriptive notes. 23–24 cm; 63–74 g. Nominative race has head, neck and upper breast glossy black, hindneck and upper mantle bright yellow, rest of mantle and back olive-yellow, rump and uppertail-coverts bright yellow; primaries blackish, edged white or grey, secondaries blackish with broad grey outer edges (forming grey panel on closed wing), secondary coverts and tertials light grey, primary coverts black with white tips (forming conspicuous white patch); tail feathers black with yellowish-olive bases and yellow tips, amount of yellow increasing from inner rectrices towards outers; lower breast to vent and undertail-coverts bright yellow; iris dark brown; bill dull red to pinkish-brown; legs blue-grey, dark grey or olive-grey. Sexes alike, but female can have red iris. Immature is like adult, but head brownish-black, streaked and mottled with yellow; iris dark brown, bill black, legs grey. Race *menelikii* differs from nominate in having less yellow and more black on tail and is rather longer-winged and shorter-tailed (easily confused in field with race *rolletii* of *O. larvatus* in S Ethiopia). **Voice.** Song “wocheelywo”, “cheelowah”, “kocheelo”, “wokachilly” or in combination “wocholee, wocheelywo” or “wocheelywo-wollawochee”; higher-pitched, less rich and less fluty than songs of other African orioles. Scolding call a short “graaa-graaa”.

Habitat. Damp highland forests, mostly between 950 m and 2000 m, e.g. gallery woodland, evergreen forests of olive (*Olea*) and *Podocarpus*, highland juniper (*Juniperus*), *Croretum* and other wet or mesic woodlands on escarpments with figs (*Ficus*) and tamarinds (*Tamarindus indica*). Avoids pure acacia (*Acacia*) woodland.

Food and Feeding. Berries, fruits, e.g. figs; also invertebrates, e.g. mantids, caterpillars. Forages alone or in pairs; gathers in flocks at certain times of year, e.g. Jun. Searches branches and foliage; also flycatches insects, such as winged termites (Isoptera).

Breeding. Nest-building in Aug in Eritrea, and young out of nest being fed with berries in Jun in Ethiopia. Nest built by female, made out of grasses, mosses and bark strips, in horizontal forked branch 2–15 m above ground. Clutch 2 eggs, white to creamy, with red-brown and lighter purplish-grey spots and blotches concentrated at obtuse end. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Locally common to abundant in its range of c. 480,000 km². Perhaps commonest in N half of range.

Bibliography. Friedmann (1937), Fry *et al.* (2000), Grant & Mackworth-Præd (1942), Hall & Moreau (1970), Mackworth-Præd & Grant (1960), Meinertzhagen (1923), Neumann (1905), Ogilvie-Grant (1904), Reichenow (1903), Rüppell (1836), Sinclair & Ryan (2003).

23. Mountain Oriole
Oriolus percivali

French: Lorient de Percival **German:** Bergpirol **Spanish:** Oropéndola Montana
Other common names: Montane/Black-tailed/Percival’s Oriole

Taxonomy. *Oriolus percivali* Ogilvie-Grant, 1903, Kikuyu Highlands, Kenya. Closely related to and sometimes treated as conspecific with *O. larvatus*, with which it may hybridize in C Kenya, but the two differ in ecology and vocalizations; both belong to the “African black-headed group”, which includes also *O. chlorocephalus*, *O. crassirostris*, *O. brachyrhynchus*, *O. monacha* and *O. nigripennis*. Monotypic.

Distribution. Montane forests of E DR Congo, Uganda, Kenya, NW Rwanda, Burundi and W Tanzania.

Descriptive notes. 19.5–21.5 cm; 60–71 g. Head to neck and upper breast are glossy black, mantle bright yellow, scapulars and back olive-green, rump olivaceous yellow; primaries blackish, narrowly edged and tipped grey-white, secondaries black with white edges and tips, tertials and greater coverts black, broadly edged and tipped yellow, median and lesser coverts yellow, primary coverts black, tipped white (conspicuous white patch on wing); central tail feathers black, remainder with yellow tips (larger on outer feathers); side of upper breast and rest of underparts intense bright yellow; iris deep red; bill brown-red or brownish-pink; legs grey or blue-grey. Sexes alike. Immature is like adult, but top and side of head streaky olivaceous black-brown, mantle olive (yellow at side) with darker streaks, chin and throat dark olive, streaked with black, merging into dull yellow breast streaked with olive; iris dark brown, bill blackish, legs light blue-grey. **Voice.** Short, fluid phrase, similar to that of *O. larvatus* but higher-pitched than that of *O. brachyrhynchus*; includes rather clipped “tyee-woh”, downslurred “ti-tyao-hoh” and longer upslurred “chit-chiluwee”. Duetting common, male giving loud “weeka-ku-weeu”, female replying with higher “weekla-wee-er”.

Habitat. Montane forest and submontane woods, well-timbered hillsides, primary and secondary evergreen forests, gallery and remnant forests, and adjacent wooded farmland, parks and gardens; between 1530 m and 3000 m.

Food and Feeding. Fruits, e.g. *Ureia* species; also invertebrates, e.g. caterpillars and hard-bodied insects. Forages alone and in pairs, also in small groups of up to six individuals (especially at fruiting trees); often joins mixed-species flocks. From middle storey to canopy, often in liana tangles; sometimes snatches food items and flycatches insects in understorey.

Breeding. Birds with enlarged gonads in May–Jun and Sept, month-old young in Aug and juveniles in Apr and Sept–Nov in DR Congo; adult feeding fledgling away from nest in Oct in Uganda. No other information.

Movements. Sedentary; perhaps some local movement.

Status and Conservation. Not globally threatened. Fairly common to common and widespread in its range of c. 83,000 km². Present in various protected areas, and classed as of least conservation concern. Occurs in montane forests in Kenya and Uganda, also common in Itombwe Mts (DR Congo) and Nyungwe Forest Reserve (Rwanda); also found in montane forests of NW Burundi, and in Mahali Mountain National Park, in W Tanzania.

Bibliography. Carswell *et al.* (2005), Chapin (1944, 1954), Fry *et al.* (2000), Hall & Moreau (1970), Jackson & Selater (1938), Mackworth-Præd & Grant (1960), McCarthy (2006), Meinertzhagen (1923), Prigogine (1978a), Short & Horne (2006), Sinclair & Ryan (2003), van Someren (1944), Zimmerman *et al.* (1996).

24. Eastern Black-headed Oriole
Oriolus larvatus

French: Lorient masqué **German:** Maskenpirol **Spanish:** Oropéndola Enmascarada
Other common names: (East) African Black-headed Oriole

Taxonomy. *Oriolus larvatus* M. H. C. Lichtenstein, 1823, “Terr. Caffror” = Cape Province, South Africa.

Closely related to and sometimes treated as conspecific with *O. percivali*, with which it may hybridize in C Kenya, but the two differ in ecology and vocalizations; both belong to the “African black-headed group”, which also includes *O. chlorocephalus*, *O. crassirostris*, *O. brachyrhynchus*, *O. monacha* and *O. nigripennis*. Race *additus* formerly known by name *tibicen*, but that name invalid, as preoccupied. Nominative race and *angolensis* appear to intergrade clineally in Zimbabwe. Proposed race *kikuyensis* (from Nairobi, in Kenya) is synonymized with *rolletii*. Five subspecies recognized.

Subspecies and Distribution.

O. l. rolletii Salvadori, 1864 – S Sudan, W & S Ethiopia, E DR Congo (to c. 2° S), Uganda, W & C Kenya, L Victoria Basin.

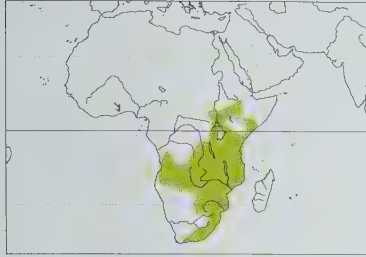

O. l. reichenowii Zedlitz, 1916 – coastal forests of Somalia to E Tanzania (S to c. 9° S).

O. l. angolensis Neumann, 1905 – Angola and N Namibia E to W Tanzania and N Mozambique.

O. l. additus Lawson, 1969 – coastal S Tanzania S to coastal S Mozambique.

O. l. larvatus M. H. C. Lichtenstein, 1823 – S Zimbabwe, inland S Mozambique, Swaziland and E South Africa (S to W Western Cape).

Descriptive notes. 20–21.5 cm; 59–72 g. Nominative race has head and neck to upper breast glossy black, mantle bright yellow, scapulars and back yellowish olive-green, rump yellow; remiges black, primaries edged and tipped grey-white, secondaries edged yellowish-grey, tertials tipped

yellow and edged olive, lesser and median coverts yellowish-olive, greater coverts broadly fringed yellowish-olive, primary coverts black, tipped white (forming conspicuous white patch on wing); central tail feathers greenish-olive to blackish, remainder black with bright yellow terminal patches, amount of yellow increasing towards outer feathers; lower breast and rest of underparts intense bright yellow; iris red; bill coral-red or brownish-red; legs slate-grey. Sexes alike. Immature is like adult, but top and side of head blackish-olive, mantle olive (yellow at side) with darker streaks, chin and throat black, streaked with yellow,

breast yellow, streaked with black; iris brown, bill blackish, legs light blue-grey. *Race angolensis* has upperparts greener than nominate, and rather smaller bill and tail; *additus* is like previous, but with shorter wing and longer bill; *rolleti* is smaller than nominate and with brighter yellow upperparts (easily confused in field with *O. monacha* in S Ethiopia); *reichenowi* is smallest, and differs from all others in having yellow areas more golden. VOICE. Song comprises wide vocabulary of liquid whistles, e.g. “ku-weeo”, “tyup, pu-wa-hoo”, “wree-ko-wuju” and “tyip-po-wheeyo”; also duets, first bird giving “pi-weeyo” or “jp-wyew-hoo”, answered by lower (sometimes glottal) “jip-bobblebob-wah” whistles. Alarm call a high, nasal downslurred “wrrreecaa”; utters loud whistling note, which turns into short grating note when alarmed. An excellent mimic, imitating many species, e.g. hawks (Accipitridae) and Olive Woodpecker (*Dendropicus griseocephalus*).

Habitat. Moist mature woodlands and forests, fairly closed-canopy deciduous woodlands in mesic savanna regions, preferably evergreen or only slightly deciduous, and especially well-timbered acacia (*Acacia*) savannas and broadleaf woodlands, e.g. miombo (*Brachystegia*), usually in vicinity of rivers, dams and other surface waters, such as gallery and coastal forests, thick coastal bush; also juniper (*Juniperus*) and thorn-scrub in Ethiopia. Also forest edge, mangroves, exotic plantations (e.g. blue gums, wattles, poplars, pines or eucalypts, even in grassland areas), mature parks, farmyards and gardens. Sea-level to 2300 m.

Food and Feeding. Small fruits and berries, e.g. of aloes (*Aloe*), *Trema*, figs (*Ficus*), loquats (*Eriobotrya japonica*), grapes (*Vitis*), mulberries (*Morus*); also nectar and pollen of aloes and *Erythrina* species, as well as hard, dry seeds. In addition, invertebrates, including grasshoppers and locusts (Orthoptera), beetles (Coleoptera), mantids, dragonflies (Odonata), honeybees (*Apis*), and both hairless and hairy caterpillars. Nestling diet mostly caterpillars of increasing size as young grow, also adult insects and dried calcium-rich millipede (Diplopoda) rings. Forages alone or in pairs, mostly in canopy, but sometimes in small groups in flowering or fruiting trees; regularly (especially immatures) joins mixed-species flocks. Invertebrates mostly gleaned; some, e.g. winged termites (Isoptera), caught by aerial flycatching. Occasionally feeds low in fruiting shrubs or on ground for caterpillars, which are habitually beaten before being swallowed.

Breeding. Breeding in Mar–Jun and Nov in Kenya, Jan–May in Uganda, Sept–Dec in Tanzania, Oct–Nov in DR Congo, Sept–Dec in Angola, Aug–Jan in Zambia, Aug–Mar in Malawi, Apr–May and Sept–Feb in Zimbabwe, Sept–Dec in Botswana and Sept–Oct in Mozambique; in South Africa, Sept–Jan in N & NE and Nov–Jan in Eastern Cape. Possible courtship displays include male standing near female with tail held fanned, wings spread and head held low, while emitting subdued notes, and noisy aerial chases. Nest built mostly or entirely by female, in 3–10 days, while male sings or calls often from nearby; a shallow to deep, open cup-nest woven mostly from old-man’s beard lichen (*Usnea*) where this available, or from grasses, mosses, tendrils and strands of pliable inner bark, lined with fine rootlets, grasses and hair, exterior camouflaged with grasses, lichens, bark, wool, string, cloth and acacia flowerheads, and sometimes bound with small amounts of spider web, external diameter 8–10 cm, height 10 cm, internal diameter 6.5–8.5 cm, depth 3.8–5.5 cm, thickness 6–8 cm; suspended hammock-like in thin, horizontal forked branch, usually in well-foliaged tree canopy at 3–20 m, away from centre of tree. Clutch 1–5 eggs, usually 2–3, pinkish or beige-grey at first, later creamy buff or white with large greyish, purplish-grey, reddish-brown, olive-brown and blackish-brown spots and streaks and some light brown blotches, concentrated at obtuse end and sometimes with grey haloes, dimensions 26.1–32.7 × 16.7–22.3 mm; incubation by female, fed on nest by male, period 14–16 days; chicks brooded mainly or entirely by female, fed by both sexes; nestling period 14–20 days. Average breeding success 1.1 fledglings per nesting attempt in Zimbabwe.

Movements. Resident, with some local movements in response to food availability; perhaps some seasonal movements, as numbers peak during Jul–Sept in E Zambia, Zimbabwe and NE South Africa.

Status and Conservation. Not globally threatened. Fairly common to common in parts of its range of c. 6,000,000 km². Breeding densities vary, generally 0.04–0.22 individuals/ha; exceptional density of 0.9 individuals/ha found in riverine forests in Tsavo East National Park, in Kenya. Occurs in various protected areas, and regarded therefore as not at any immediate risk.

Bibliography. Archer (1992), Ash & Miskell (1998), Barry (1998), Baumann (2001), Brooke (1962, 1965, 1970a, 1986), Clancey (1996), Cyrus & Robson (1980), Dean (2000), Dowsett *et al.* (2008), Dowsett-Lemaire (1989b), Dowsett-Lemaire & Dowsett (2006), Dunning (1993), Ellenberger (1951), Fry *et al.* (2000), Ginn (1989), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Hockey *et al.* (2005), Howells (1985), Jackson & Selator (1938), Lack (1985), Mackworth-Præd & Grant (1960, 1963, 1973), McCarthy (2006), Neumann (1905), Nikolaus (1987), Nixon (1992), Oatley (1969), Oatley & Skead (1972), Parker (2005), Patten (2002), Priest (1936), Reichenow (1903), Rudnai (1994), Schönwetter & Meise (1983), Short & Horne (2006), Sinclair & Ryan (2003), Skinner (1995), van Someren (1956), Tarboton (2001), Vernon (1973, 1988), Vincent (1936), Zimmerman *et al.* (1996).

25. Black-winged Oriole

Oriolus nigripennis

French: Lorient à ailes noires **German:** Schwarzflügelpirol **Spanish:** Oropéndola Alinegra

Taxonomy. *Oriolus nigripennis* J. Verreaux and É. Verreaux, 1855, Gabon River. Belongs to the “African black-headed group”, which also includes *O. chlorocephalus*, *O. crassirostris*, *O. brachyrhynchus*, *O. monacha*, *O. percivali* and *O. larvatus*. Proposed race *leucostictus* (described from Beni, in NE DR Congo) synonymized with nominate. Boundary between the two races uncertain, but probably R Niger, in Nigeria. Species often treated as monotypic. Two subspecies tentatively recognized.

Subspecies and Distribution.

O. n. alleni Amadon, 1953 – Sierra Leone and SE Guinea E to SW Nigeria.
O. n. nigripennis J. Verreaux & É. Verreaux, 1855 – SE Nigeria and S Cameroon E to S Sudan and NW Uganda, S to NW Angola; also Bioko I (Fernando Póo).

Descriptive notes. 19–21 cm; 50–60 g. Nominata race has head to neck and upper breast glossy black, hindneck and upper mantle bright golden-yellow, becoming yellowish olive-green on lower

and throat yellow with blackish streaks, breast dark-streaked olive-green; iris brown, bill brown or pinkish-brown. Race *alleni* is smaller than nominate, with upperparts yellowish-green or olive, not golden-yellow. VOICE. Vocabulary very varied, and similar to that of *O. brachyrhynchus* but higher-pitched, with rapid changes in pitch and intensity, some notes merging into others and leaving fewer gaps. Song phrases often turn into duets, an initial short “teeyup” answered by “co-wah” or a glottal “woo-t’i-wah”; also upslurred “ko-lip” (said to be distinct from calls of *O. brachyrhynchus*) and downslurred “tyi-who”, double “wah-wah” (like distant barking dog), “hoo-whee” or “hoo-weehoo”, often repeated, also “hee-haha”, a measured “ho, hee, her, kohor” and a deeper “hou-you-kyuwor”. Scolding call a nasal “tyipu-wrrraaya” with no change in pitch.

Habitat. Mature secondary forest, forest edge, gallery forest, coffee forest, mangroves, large trees in plantations and clearings; also around villages and in used or recently abandoned native cultivation which is overgrown with bush; found less often in primary forest. Sea-level to 2150 m.

Food and Feeding. Small fruits, e.g. figs (*Ficus*), *Musanga* and *Rauvolfia*; also invertebrates, e.g. beetles (Coleoptera), winged ants (Formicidae), butterflies (Lepidoptera), small orthopterans, but especially caterpillars. Forages alone, in pairs or in groups of up to four individuals; sometimes joins mixed-species flocks. Searches in dense foliage from middle storey up to canopy. Caterpillars gleaned from leaves and branches, sometimes from undersides of leaves during hovering flight.

Breeding. Fledgling in Jan in Guinea, birds with enlarged gonads in Sept in Liberia, and nest-building in Jan and full-grown young in Jun in Ivory Coast; nesting in Feb in Ghana and breeds in Mar–Jun in Nigeria; eggs in Feb and nestlings in Oct in Cameroon; breeding condition in Sept, nest-building in Oct, Dec and Feb, and juveniles in Dec in Gabon; enlarged gonads in Feb in Angola; breeding in Jul–Nov and immature in Dec in DR Congo, and breeding condition in Oct and Jan in S Sudan. Breeding partners chase away conspecifics and other bird species, e.g. *O. brachyrhynchus*. In possible courtship display, singing male adopts posture with tail spread and neck puffed out and held erect. One nest in Gabon was an open cup woven from grasses and fibres, with mosses and *Usnea* lichen worked into the exterior, suspended hammock-like in horizontal fork near end of branch 22 m up in a fig tree. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Generally common and widespread in range of c. 1,900,000 km². Estimated density 0.04–0.1 individuals/ha at M’Passa, in Gabon. Occurs in various protected areas, e.g. Mont Nimba Strict Nature Reserve, in Ivory Coast, Korup National Park, in Cameroon, Dzanga Reserves, in Central African Republic, Odzala and Nouabalé-Ndoki National Parks, in PR Congo, and others.

Bibliography. Borrow & Demey (2001), Chapin (1954), Dean (2000), Dunning (1993), van den Elzen (1975), Fotso (1996), Fry *et al.* (2000), Greig-Smith (1977), Grimes (1987), Hall & Moreau (1970), Mackworth-Præd & Grant (1960, 1973), McCarthy (2006), Meinertzhagen (1923), Nikolaus (1987), Reichenow (1903), Sinclair & Ryan (2003), White (1962).

26. Black-hooded Oriole

Oriolus xanthornus

French: Lorient à capuchon noir **German:** Schwarzkopfpörl **Spanish:** Oropéndola Encapuchada
Other common names: (Asian/Oriental/Indian) Black-headed Oriole; Ceylon Black-headed Oriole (*ceylonensis*)

Taxonomy. *Coracias Xanthornus* Linnaeus, 1758, “America”; error = “Bengal”, north-east India. A member of the “Asian black-headed group”, which also includes *O. hosii*, *O. cruentus*, *O. trillii* and *O. mellianus*. Nomenclature of races in Indian Subcontinent uncertain because of uncertainty over precise location of type locality. Race *reubenii* formerly referred to by name *andamanensis*, but latter name invalid, as preoccupied; perhaps better merged with *ceylonensis*. Proposed race *thaiacous* (described from Koh-Lak, in SW Thailand) synonymized with nominate. Five subspecies currently recognized.

Subspecies and Distribution.

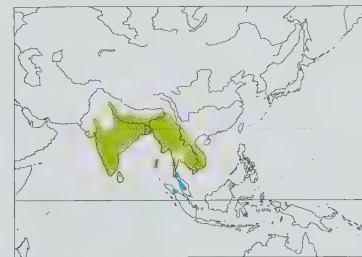

O. x. xanthornus (Linnaeus, 1758) – N India (Himalayan foothills) and S Nepal E to Myanmar and S China (S Yunnan), S to N & S Thailand, N Peninsular Malaysia (Langkawi I only) and Indochina (except N Vietnam).

O. x. maderaspatanus Franklin, 1831 – Ganges plain and peninsular India.

O. x. ceylonensis Bonaparte, 1850 – Sri Lanka.

O. x. reubenii Abdulali, 1977 – Andaman Is.

O. x. tanakae Nagamichi Kuroda, 1925 – NE Borneo (SE Sabah and adjoining Kalimantan) and adjacent islands.

of central tail feathers dark olive-green, throat dusky white with dark streaks. Race *maderaspatanus* is smaller than nominate, yellow on inner secondaries and tertiaries reduced to terminal spots; *ceylonensis* is smallest, and similarly has reduced yellow on inner secondaries and tertiaries; *reubenii*

mantle and back; rump and uppertail-coverts bright olivaceous yellow; flight-feathers black, primaries with narrow whitish edges, secondaries with broad olive-yellow edging, most of upwinging-coverts golden-yellow, primary coverts black; central tail feathers black, remainder with yellow tips increasing in extent towards outer feathers, outermost almost all yellow; side of upper breast and rest of underparts intense bright yellow; iris crimson or dark red; bill red-brown or pinkish-brown; legs grey or bluish-grey. Sexes alike. Immature has head olive-yellow, showing black as adult feathers emerge; upperparts olive-green, chin

and throat yellow with blackish streaks, breast dark-streaked olive-green; iris brown, bill brown or pinkish-brown. Race *alleni* is smaller than nominate, with upperparts yellowish-green or olive, not golden-yellow. VOICE. Vocabulary very varied, and similar to that of *O. brachyrhynchus* but higher-pitched, with rapid changes in pitch and intensity, some notes merging into others and leaving fewer gaps. Song phrases often turn into duets, an initial short “teeyup” answered by “co-wah” or a glottal “woo-t’i-wah”; also upslurred “ko-lip” (said to be distinct from calls of *O. brachyrhynchus*) and downslurred “tyi-who”, double “wah-wah” (like distant barking dog), “hoo-whee” or “hoo-weehoo”, often repeated, also “hee-haha”, a measured “ho, hee, her, kohor” and a deeper “hou-you-kyuwor”. Scolding call a nasal “tyipu-wrrraaya” with no change in pitch.

Habitat. Mature secondary forest, forest edge, gallery forest, coffee forest, mangroves, large trees in plantations and clearings; also around villages and in used or recently abandoned native cultivation which is overgrown with bush; found less often in primary forest. Sea-level to 2150 m.

Food and Feeding. Small fruits, e.g. figs (*Ficus*), *Musanga* and *Rauvolfia*; also invertebrates, e.g. beetles (Coleoptera), winged ants (Formicidae), butterflies (Lepidoptera), small orthopterans, but especially caterpillars. Forages alone, in pairs or in groups of up to four individuals; sometimes joins mixed-species flocks. Searches in dense foliage from middle storey up to canopy. Caterpillars gleaned from leaves and branches, sometimes from undersides of leaves during hovering flight.

Breeding. Fledgling in Jan in Guinea, birds with enlarged gonads in Sept in Liberia, and nest-building in Jan and full-grown young in Jun in Ivory Coast; nesting in Feb in Ghana and breeds in Mar–Jun in Nigeria; eggs in Feb and nestlings in Oct in Cameroon; breeding condition in Sept, nest-building in Oct, Dec and Feb, and juveniles in Dec in Gabon; enlarged gonads in Feb in Angola; breeding in Jul–Nov and immature in Dec in DR Congo, and breeding condition in Oct and Jan in S Sudan. Breeding partners chase away conspecifics and other bird species, e.g. *O. brachyrhynchus*. In possible courtship display, singing male adopts posture with tail spread and neck puffed out and held erect. One nest in Gabon was an open cup woven from grasses and fibres, with mosses and *Usnea* lichen worked into the exterior, suspended hammock-like in horizontal fork near end of branch 22 m up in a fig tree. No other information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Generally common and widespread in range of c. 1,900,000 km². Estimated density 0.04–0.1 individuals/ha at M’Passa, in Gabon. Occurs in various protected areas, e.g. Mont Nimba Strict Nature Reserve, in Ivory Coast, Korup National Park, in Cameroon, Dzanga Reserves, in Central African Republic, Odzala and Nouabalé-Ndoki National Parks, in PR Congo, and others.

Bibliography. Borrow & Demey (2001), Chapin (1954), Dean (2000), Dunning (1993), van den Elzen (1975), Fotso (1996), Fry *et al.* (2000), Greig-Smith (1977), Grimes (1987), Hall & Moreau (1970), Mackworth-Præd & Grant (1960, 1973), McCarthy (2006), Meinertzhagen (1923), Nikolaus (1987), Reichenow (1903), Sinclair & Ryan (2003), White (1962).

26. Black-hooded Oriole

Oriolus xanthornus

French: Lorient à capuchon noir **German:** Schwarzkopfpörl **Spanish:** Oropéndola Encapuchada
Other common names: (Asian/Oriental/Indian) Black-headed Oriole; Ceylon Black-headed Oriole (*ceylonensis*)

Taxonomy. *Coracias Xanthornus* Linnaeus, 1758, “America”; error = “Bengal”, north-east India. A member of the “Asian black-headed group”, which also includes *O. hosii*, *O. cruentus*, *O. trillii* and *O. mellianus*. Nomenclature of races in Indian Subcontinent uncertain because of uncertainty over precise location of type locality. Race *reubenii* formerly referred to by name *andamanensis*, but latter name invalid, as preoccupied; perhaps better merged with *ceylonensis*. Proposed race *thaiacous* (described from Koh-Lak, in SW Thailand) synonymized with nominate. Five subspecies currently recognized.

Subspecies and Distribution.

O. x. xanthornus (Linnaeus, 1758) – N India (Himalayan foothills) and S Nepal E to Myanmar and S China (S Yunnan), S to N & S Thailand, N Peninsular Malaysia (Langkawi I only) and Indochina (except N Vietnam).

O. x. maderaspatanus Franklin, 1831 – Ganges plain and peninsular India.

O. x. ceylonensis Bonaparte, 1850 – Sri Lanka.

O. x. reubenii Abdulali, 1977 – Andaman Is.

O. x. tanakae Nagamichi Kuroda, 1925 – NE Borneo (SE Sabah and adjoining Kalimantan) and adjacent islands.

Descriptive notes. 23–25 cm; 46–79 g. Male nominate race has head, neck and upper chest glossy black, rest of body and upwinging-coverts bright golden-yellow; rest of wing black, primaries narrowly edged whitish and tipped yellowish, primary coverts, secondaries and tertiaries black with yellow edging; tail feathers have basal half yellow, distal half black with golden-yellow tips, although three outer rectrices sometimes entirely golden-yellow; iris red; bill pink; legs grey. Female is as male, but duller above. Immature is like adult, but forehead with yellowish streaks (sometimes completely yellow), whitish eye-ring, outer half

is small, as previous, but deeper yellow; *tanakae* has four (rather than three) outer tail feathers entirely yellow. **Voice.** Song of liquid fluty whistles, very varied and differing among races, “tu-u-u-liu”, “hu-kwia-lu”, middle syllable stressed, “kwek-hu-kelu”, last syllable stressed and first audible only at close quarters; 4-note “yu-hu-a-yu”, answered by 3-note “tu-hu-ee” or a resonant and penetrating “ti-too”; male may give extended broken song for up to 15 minutes as a syncopated jumble of mellow fluty notes interspersed with harsh nasal phrases. Alarm a hoarse mewling “cheeah” and a harsh nasal “kwaak”.

Habitat. Dry dipterocarp forest and mixed deciduous moist woodlands, open semi-evergreen and evergreen forests, swamp-forest, mangroves, mature second growth, forest edge, scrub, plantations, orchards, mango (*Mangifera*) groves, avenue trees, parks, village groves, gardens, and other cultivated areas. Usually below 1200 m, but sometimes up to 1800 m in India, Sri Lanka, Bhutan and Nepal; to 1000 m in China, Thailand and Borneo.

Food and Feeding. Mainly berries and fruits, especially figs (*Ficus*), notably peepal (*Ficus religiosa*); also some nectar, e.g. of *Salmalia*, *Bombax* and *Erythrina*; also insects, e.g. hemipteran bugs, weevils (*Curculionidae*), ants (*Formicidae*), moths (*Lepidoptera*) and hairy caterpillars, and flying termites (*Isoptera*). Nestlings fed with gnats and other small insects, later with small caterpillars. Forages alone, in pairs or, after breeding season, in small flocks; sometimes joins mixed-species flocks. Feeds generally high in trees; sometimes descends to ground to take insects.

Breeding. Breeding throughout year, with local variations; two or more broods per season. Possible courtship displays include frequent aerial chases. Deep cup-nest built by both sexes, of leaves, grasses, thin strips of bark and other vegetable fibres, lined with very fine twigs or grasses, decorated on outside with lichens, woolly fibres, leaves, bark flakes and the like, internal diameter 7–8 cm, internal depth 5–1 cm, suspended hammock-like in thin, horizontal forked branch at various heights, usually high in outer edge of well-foliaged tree canopy, and often close to nest of Black Drongo (*Dicrurus macrocerus*). Clutch 2–4 eggs, usually 3, white to pinkish-white or creamy with a few pinkish-brown, reddish-brown or purplish-grey spots and streaks, darker and more concentrated at obtuse end and sometimes surrounded by reddish-pink to ink-purple haloes, dimensions 23.5–33.3 × 18–22 mm; both sexes incubate eggs and tend chicks, no information on duration of incubation and nestling periods; after young fledge, family-members stay together for brief period.

Movements. Generally resident, but some local movements reported in India and Nepal, e.g. upward migration in summer. Nominate race apparently only a non-breeding winter visitor Oct–Apr in N Peninsular Malaysia and Sumatra, and one vagrant recorded W Borneo (SW Sarawak).

Status and Conservation. Not globally threatened. Common in parts of its range, which covers c. 1,000,000–10,000,000 km². Occurs in various protected areas through most of range, and considered not at any immediate risk.

Bibliography. Ali & Ripley (1972a), Chen Fuguan *et al.* (1998), Dharmakumarsinhji (1954), Dickinson (2004), Dunning (1993, 2008), Eve & Guigues (1996), Fleming *et al.* (1984), Fletcher & Inglis (1936), Grewal (1993), Grimmett *et al.* (1998), Henry (1998), Hume & Oates (1889), Inskipp & Inskipp (1991), Jeyarajasingam & Pearson (1999), Kazmierczak (2000), King *et al.* (1975), Lekagul & Round (1991), Lowther (1949), MacKinnon & Phillips (1993, 2000), Majumdar (1980), van Marle & Voous (1988), Medway & Wells (1976), Meinertzhagen (1923), Rasmussen & Anderton (2005b), Ripley (1982), Robson (2000b), Schönwetter & Meise (1983), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Stuart Baker (1926), Wells (2007), Whistler & Kinnear (1949).

27. Black Oriole

Oriolus hosii

French: Lorient noir

German: Mohrenpirol

Spanish: Oropéndola Negra

Taxonomy. *Oriolus hosii* Sharpe, 1892, Mount Dulit, Sarawak, Borneo.

Closely related to *O. cruentus*, *O. traillii* and *O. mellianus*; all of these, together with *O. xanthornus*, form the “Asian black-headed group”. Species name sometimes misspelled “*hosei*”. Monotypic.

Distribution. Montane forests of NW Borneo.

Descriptive notes. 21.5 cm. Male is entirely black with slight gloss, except for deep chestnut undertail-coverts; iris dull crimson; bill dull pink; legs grey to greyish-black. Female is like male, except that lower chest and belly are dark slate-grey, rather than black, and contrast (not sharply) with black head, upper breast and upperparts. Immature resembles female. **Voice.** Clear whistles with downward inflection.

Habitat. Montane forest and mossy transitional forest, from 900 m to 2000 m, but especially between 1100 and 1200 m on sandy N side of Dulit range.

Food and Feeding. Fruits, berries, also invertebrates, e.g. termites (*Isoptera*). Quietly forages alone, in pairs or in small groups, in canopy, rarely coming to ground.

Breeding. No information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Bornean Mountains EBA. Confined to small montane range in Sarawak, with records from only six localities. Most montane forests in region remain relatively pristine, but some recent human encroachment into this species' range may have caused some population decline. It should nevertheless be secure in several protected areas, e.g. Gunung Mulu National Park, and several others that have been officially listed.

Bibliography. Anon. (2007g), Butchart & Stattersfield (2004), Collar *et al.* (2001), Hose (1893), MacKinnon & Phillips (1993), Meinertzhagen (1923), Smythies (1960), Smythies & Davison (1999), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

28. Black-and-crimson Oriole

Oriolus cruentus

French: Lorient ensanglanté

German: Rotbrustpirol

Spanish: Oropéndola Ensangrentada

Other common names: Crimson-breasted Oriole

Taxonomy. *Leptopteryx cruenta* Wagler, 1827, Java.

Closely related to *O. hosii*, *O. traillii* and *O. mellianus*; all, together with *O. xanthornus*, form the “Asian black-headed group”. Four subspecies recognized.

Subspecies and Distribution.

O. c. malayanus Robinson & Kloss, 1923 – Peninsular Malaysia.

O. c. consanguineus (R. G. W. Ramsay, 1881) – mainland Sumatra.

O. c. cruentus (Wagler, 1827) – Java.

O. c. vulneratus Sharpe, 1887 – N & C Borneo.

Descriptive notes. 21–24 cm. Male nominate race has plumage entirely black with bluish gloss, except for dark crimson patch (longer than it is broad) on breast and upper belly; wing dark brown, primary coverts tipped dark crimson (forming small wing patch); iris dark brown; bill light blue-grey with small dark tip; legs grey. Female is as male, but breast patch more orange-red than crimson. Immature is sooty black, with greyish tinge on lower breast and belly; immature male has a few scattered crimson breast feathers. Race *malayanus* is larger than nominate and has much larger square-shaped crimson breast patch extending

full width of breast, primary coverts entirely crimson (larger wing patch), also sexually dichromatic, female black with slight blue gloss above, sooty black-brown and with no trace of red below; *consanguineus* is like a smaller version of previous race, having large square crimson breast patch and almost entirely crimson primary coverts, also sexually dichromatic, female slightly glossy blue-black above and sooty grey with brownish-black mottling below; *vulneratus* is smaller than nominate and male has entirely red primary coverts, larger extent of crimson on breast (but less than in preceding two), sexes very similar but female has less extensive crimson on breast, and primary coverts only tipped and fringed red. **Voice.** A short melodious call and harder “kek kree, kree kek”; also a sharp, harsh, shrill, cat-like descending mew, “keeeuu”, and a rather similar “squee-eh”, repeated after several seconds.

Habitat. Broadleaf evergreen forest, moss forest and forest edge, especially in creeper-covered trees; in Sumatra, in montane primary forest and mature secondary forest and edges, but also in low bushes in moss forest up to mountain summits; in hill and montane forests in Java. At 900–1500 m (once at 600 m) in Peninsular Malaysia, 500–2400 m in Sumatra, 1200–1800 m in Java, and between 600 m and 2300 m in Borneo.

Food and Feeding. Berries and fruits, e.g. of Melastomataceae and figs (*Ficus*), also insects, e.g. beetle larvae (*Coleoptera*), termites (*Isoptera*), both hairy and hairless caterpillars. Even leaf buds, e.g. of rhododendrons (*Rhododendron*), taken. Forages alone or in pairs, rarely in small groups, from understory to canopy; often in vine tangles or low in bushes in moss forests on mountain summits, and sometimes even on ground. Often joins mixed-species flocks, when it flycatches insects in middle storey, canopy and above.

Breeding. Birds in breeding condition in Feb and Jul and evidence of breeding Mar and Jun–Aug in Peninsular Malaysia, nestlings in Jun in Sumatra, and fledglings in Mar in N Borneo (Sabah). Nest a deep cup woven from grasses, bryophytes and small twigs, suspended hammock-like beneath thin, horizontal forked branch high in outer edge of canopy foliage, two nests recorded at 8–10 m. No information on clutch size, eggs white with a few sparse purplish-black spots concentrated on obtuse end, 32.3 × 22.2 mm; one brood apparently of two nestlings, tended by both parents. No further information.

Movements. Presumed sedentary.

Status and Conservation. Not globally threatened. Uncommon to fairly common in parts of its range, estimated to cover c. 1,000,000–10,000,000 km². Occurs in various protected areas, e.g. Fraser's Hill Wildlife Reserve, in Peninsular Malaysia, Kinabalu Park, in Sabah (N Borneo), and several others. Is sometimes sold in cagebird trade.

Bibliography. Davison (1992), Glenister (1985), Jeyarajasingam & Pearson (1999), King *et al.* (1975), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Voous (1988), Meinertzhagen (1923), Robson (2000b), Schönwetter & Meise (1983), Sheldon *et al.* (2001), Shepherd *et al.* (2004), Smythies (1960), Smythies & Davison (1999), Strange & Jeyarajasingam (1993), Wells (2007).

29. Maroon Oriole

Oriolus traillii

French: Lorient pourpré

German: Blutpirol

Spanish: Oropéndola Granate

Taxonomy. *Pastor Traillii* Vigors, 1832, no locality = Darjeeling, north India.

Closely related to *O. hosii*, *O. cruentus* and, especially, *O. mellianus*; all, together with *O. xanthornus*, form the “Asian black-headed group”. Four subspecies recognized.

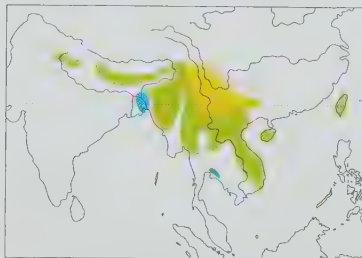

Subspecies and Distribution.

O. t. traillii (Vigors, 1832) – Himalayas, Myanmar, S China (Yunnan E to SE Guizhou and W Guangxi), N Thailand, N Laos and N Vietnam.

O. t. robinsoni Delacour, 1927 – S Laos and S Vietnam.

O. t. nigellicauda (Swinhoe, 1870) – Hainan I.

O. t. ardens (Swinhoe, 1862) – Taiwan.

Descriptive notes. 25.5–28 cm; 67–81 g. Male nominate race has head and neck to upper mantle and upper breast entirely glossy black, rest of body deep metallic maroon; upperwing glossy black, tail pale maroon; iris creamy white; bill pale blue-grey; legs pale blue. Female has head blackish-brown, merging above into dark brown mantle (sometimes with maroon wash), rump maroon-chestnut; wing dark brown with paler edging, central tail feathers maroon-brown, outer rectrices paler brownish-maroon on inner webs; throat, breast and belly whitish with traces of maroon wash, all heavily streaked with blackish, undertail-coverts

maroon; in some birds, chin to upper breast black; bare parts as male. Immature male is similar to female, but head and throat black, back darker than female, and chest to belly streaked maroon and black; iris brown. Male *robinsoni* is smaller and a lighter, more crimson maroon than nominate; *nigellicauda* differs from nominate in being bright crimson with little gloss, rather than metallic glossy maroon; *ardens* is like previous but larger, and with rather stouter bill. **Voice.** Harsh “keeah” or “ko-kay-wa”, usually followed by rich liquid fluty whistles, “pi-io-io”; also a nasal miaowing “nyaoooooow”.

Habitat. Dense moist deciduous, semi-evergreen or evergreen forests and forest edge, e.g. oak (*Quercus*) forests or subtropical pine (*Pinus*) forests; moves into more deciduous forests and adjacent plantations in winter. Up to 4000 m in China, but only to 2500 m in Nepal and Bhutan and 800 m in Thailand; lower in non-breeding season, e.g. 1200–2100 m in winter in Nepal.

Food and Feeding. Nectar, berries, fruits, especially figs (*Ficus*), and invertebrates, e.g. caterpillars. Forages secretively, alone, in pairs or in small flocks, from middle storey up to canopy; sometimes descends to understorey or ground. Often joins mixed-species flocks.

Breeding. Breeds Apr–Jun in India and Mar in Myanmar. Nest, built by both sexes, a deep cup woven from bark and other vegetable fibres, grass stems, tendrils, bamboo sheaths, leaves and green mosses, lined with fine grasses and rootlets, bound with cobwebs, external diameter 12.7 cm, height 7–8.9 cm, internal diameter 8.3–10.1 cm, depth 5.1–6.4 cm, suspended hammock-like from thin, horizontal forked branch usually high in outer edge of well-foliaged tree canopy. Clutch 2–3 eggs, white with creamy or pink tinge, with reddish-brown, dark purplish-brown or blackish spots and streaks concentrated at obtuse end and surrounded by brownish-red haloes, dimensions 26.3–30.7 × 18.1–21.7 mm; both sexes incubate eggs and tend chicks, no information on duration of incubation and nestling periods.

Movements. Some altitudinal movement. In cold weather and during winter, individuals move from summer elevations to lower altitudes (below 1800 m), so that some passage or wintering birds regularly found in lowlands of Bangladesh, N Laos, Tonkin, N Annam or Thailand.

Status and Conservation. Not globally threatened. Fairly common to common in most parts of its range of c. 1,000,000–10,000,000 km². Occurs in various protected areas in breeding range, e.g. Diding Nature Reserve (Guangxi).

Bibliography. Ali & Ripley (1972a), Chen Fuguan *et al.* (1998), Cheng Tsohsin (1987), Dunning (1993), Échécopar & Hile (1983), Eve & Guigüe (1996), Fleming *et al.* (1984), Grimmett *et al.* (1998), Hume & Oates (1889), Inskipp & Inskipp (1991), Inskipp *et al.* (1999), Jerdon (1863), Kazmierczak (2000), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), MacKinnon & Philipps (2000), Meinertzhagen (1923), Meyer de Schauensee (1984), Rand & Fleming (1957), Rasmussen & Anderton (2005b), Ripley (1982), Robson (2000b), Round & Nadee (2001), Schönwetter & Meise (1983), Smythies (1986), Stuart Baker (1926), Yan Chongwei & Xu Weishu (1996).

30. Silver Oriole
Oriolus mellianus

French: Loriot argenté **German:** Seidenpirol **Spanish:** Oropéndola Plateada
Other common names: Stresemann's/Mell's (Maroon) Oriole

Taxonomy. *Oriolus traillii melliianus* Stresemann, 1922, Drachenkopf, Guangdong Province, south-east China.

Closely related to *O. hosii*, *O. cruentus* and, especially, *O. traillii*; all, together with *O. xanthornus*, form the "Asian black-headed group". Monotypic.

Distribution. Breeds in SC China (SC Sichuan, NE Yunnan, Guizhou, N Guangxi, N Guangdong); non-breeding SE Thailand and W Cambodia.

Descriptive notes. 28 cm. Male has head, neck and throat glossy jet-black, rest of body silvery white, with some deep maroon spots (usually hidden), undertail-coverts whitish to pink; wing all black, tail feathers maroon with silvery edging; iris pale yellow; bill bluish-grey; legs pale bluish-grey. Female has head and neck black, contrasting sharply with dark grey mantle with darker streaks, rump slightly browner; wing all dark blackish-brown, tail maroon; chin and throat white with heavy black streaking and spotting, breast white with dark grey streaks, undertail-coverts pink;

Food and Feeding. Diet presumably insects and fruit; seen to take nectar from *Erythrina* tree in non-breeding season (Thailand). Forages alone or in pairs in canopy; sometimes joins mixed-species flocks.

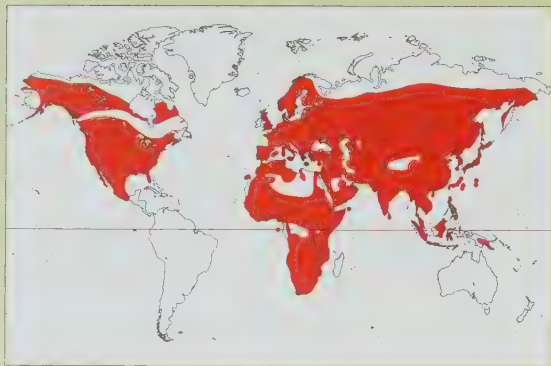

Breeding. Breeds Apr–Aug. Pre-breeding activities, such as dawn song, display, pair-bonding flights and territorial chases, observed from late Apr until early May in Nanling National Nature Reserve (Guangdong), and a female on nest as well as a nest under construction 20 m up in moderately mature *Sorbus folgneri* tree in May. No other information.

Movements. Migratory. Arrives at Chinese breeding sites in Apr and leaves in Oct at latest; arrival at non-breeding sites in Thailand and Cambodia in Oct, departure in Apr.

Status and Conservation. **VULNERABLE.** Restricted-range species: present in Chinese Sub-tropical Forests EBA. Has relatively small breeding range (c. 28,000 km²) and presumably small, declining and fragmenting population of fewer than 10,000 individuals following widespread habitat loss, degradation and fragmentation in both breeding and wintering ranges. Was considered to be fairly to very common in 1930s, but recent extensive habitat loss implies that species has undergone a rapid population decline. Currently known from only 22 breeding localities (15 post-1980) in SC Sichuan, Yunnan, Guizhou, N Guangxi and N Guangdong, in SE China, and from twelve wintering localities (seven post-1980) in Thailand and SW Cambodia. Still locally common in Sichuan, where a flock of 40 individuals recorded in 1988 and estimated density of 1.5 birds/km²; up to nine birds recently recorded at several localities in Guangxi and Guangdong. Main threat is ongoing forest loss, degradation and fragmentation in both breeding and wintering ranges through timber extraction (both legal and illegal), construction of hydro-electric power stations, conversion to agriculture and uncontrolled fires, even in some protected areas. Most of remaining primary forests in S Sichuan are scheduled for logging in the next 20 years, but a recent logging ban in upper Yangtze basin appears to have led to a complete halt to deforestation. The species is legally protected in Thailand. It has been recorded from at least eight protected areas in China, e.g. Nanling National Nature Reserve (Guangdong) and Mao'er Shan Nature Reserve (Guangxi), and six in Thailand, but some protected areas are now completely isolated forest patches and face further degradation through human encroachment coupled with inadequate management.

Bibliography. Anon. (2007g), Buchart & Stattersfield (2004), Chen Fuguan *et al.* (1998), Collar, Andreev *et al.* (2001), Collar, Crosby & Stattersfield (1994), Crosby (1991), Dickinson (2004), Eve & Guigüe (1996), Kilburn (2004), King *et al.* (1975), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), MacKinnon & Philipps (2000), Meyer de Schauensee (1984), Pilgrim & Pierce (2006), Riley (1938), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stresemann (1931b).

Class AVES
Order PASSERIFORMES
Suborder OSCINES
Family LANIIDAE (SHRIKES)

- Small to rather large, slender-bodied, short-necked passerines with rounded wings, longish tail, bill with tomial tooth, prominent rectal bristles; plumage generally sombre.
- 14–50 cm.

- North America, Europe, Asia and Africa.
- Grassland, open country, bushy areas, fallow fields, one species in forest.
- 3 genera, 31 species, 99 taxa.
- 1 species threatened; none extinct since 1600.

Systematics

The family Laniidae is a comparatively small group of ten-primaried passerines. It is widespread in Africa, Asia, Europe and North America, but absent from South America and Australia, as well as from Antarctica.

The origins of the shrikes are subject to debate. It has been suggested that during the Miocene, about 24 million years ago, the continent that is now Africa had a relict Eurasian avifauna and that shrikes were part of the radiation. An African origin has been proposed on the basis of plumage characteristics, and is supported by the hypothesis that Palearctic migration had its origins in Africa. Recent evidence, however, indicates that the shrikes may have originated in the Australasian region during the Tertiary period. The earliest shrike-like fossil, *Lanius miocaenus*, is from the Lower Miocene of Europe. The first attempts at a logical classification of birds, carried out by F. Willughby, by C. Linnaeus, and by J. Latham in the seventeenth and eighteenth centuries, included reasonably good descriptions of the European laniids.

A similarity of sperm shape to that of the corvids provides an important clue to the ancestry of the shrikes. This is further substantiated by the results of genetic and behavioural studies, which support the idea of a common corvid ancestor.

Some classifications have included the bush-shrikes (Malaconotidae) or the helmet-shrikes (Prionopidae), or both, as subfamilies within the Laniidae, the “true” shrikes then being treated as the third subfamily of the latter. Although such treatment has found favour with a number of recent taxonomists, both the bush-shrikes and the helmet-shrikes exhibit significant differences from laniids in morphology and behaviour, and it seems better to treat these three groups as representing three distinct families.

Apart from the 27 shrike species in the genus *Lanius*, the family as presently constituted contains the very long-tailed Yellow-billed Shrike (*Corvinella corvina*) and Magpie Shrike (*Corvinella melanoleuca*), both of which look different and have in the past caused taxonomic confusion. On the basis of their cranial morphology and jaw and hind-limb anatomy, and on the results of DNA–DNA hybridization studies, they are close to both the *Lanius* shrikes and the white-crowned shrikes of the genus *Eurocephalus*. They differ, however, in the fact that they produce vocal duets, as well as in several aspects of behaviour, including co-operative breeding and gregariousness, with groups of a dozen individuals occurring; moreover, they do not impale prey in the

manner of *Lanius* shrikes. Likewise, the two African white-crowned species, the Southern White-crowned Shrike (*Eurocephalus anguitimens*) and the Northern White-crowned Shrike (*Eurocephalus ruppelli*), are distinctive. They were once combined as one species, but all recent authorities now agree that they represent two separate species on the grounds primarily of plumage differences between them, coupled with their discrete distributional ranges. It has been suggested that they form a superspecies. According to research based on DNA–DNA hybridization, the *Eurocephalus* shrikes are close to the shrikes of the genus *Lanius*. Of all genera currently considered to comprise the family Laniidae, *Eurocephalus* is the least “shrike-like”. Its anatomical and behavioural characteristics suggest that its two members are the most primitive of the shrikes.

Although recent authors place *Eurocephalus* in the family Laniidae, others have pointed out that these two white-crowned shrikes build neat, compact, well-camouflaged nests like those of the prionopid helmet-shrikes, and unlike the nests of *Lanius* shrikes in Africa. In addition, and again in contrast to *Lanius*, they have scutellation extending down the sides of the tarsus, as well as the front of it. They are generally sedentary, occurring primarily in pairs or in small family groups, instead of in flocks. Like *Lanius* shrikes, they capture their prey mainly from the ground.

True shrikes are well represented in sub-Saharan Africa. The genus *Corvinella* is confined to that region, but the most widespread sub-Saharan species is the Common Fiscal (*Lanius collaris*), which, with seven subspecies, can be seen almost everywhere in suitable habitats in the region. The rarest species is the rather similar Newton's Fiscal (*Lanius newtoni*), restricted to the island of São Tomé, in the Gulf of Guinea. Two *Lanius* species breed both in North Africa and in Eurasia, namely the Southern Grey Shrike (*Lanius meridionalis*) and the Woodchat Shrike (*Lanius senator*), and the latter also migrates from Eurasia to Africa, as do populations of four other *Lanius* species. Other shrikes of this genus are common in Asia, and the subspecies *stresemanni* of the Long-tailed Shrike (*Lanius schach*) breeds in New Guinea. Only two species have reached North America. The Holarctic Great Grey Shrike (*Lanius excubitor*) has some breeding populations beyond the Arctic Circle and breeds in Alaska and northern Canada, as well as in northern, middle and south-east Europe and north, central and east Asia, and the very similar Loggerhead Shrike (*Lanius ludovicianus*) is found only in North America and Mexico.

The uniformity of the *Lanius* species has led to much debate and little consensus over their relationships within the genus. An example of such confusion is that of the “brown” shrikes, which have at different times been lumped into a single species or split into at least three separate species, the Brown Shrike (*Lanius cristatus*), the Red-backed Shrike (*Lanius collurio*) and the Isabelline Shrike (*Lanius isabellinus*). To confuse matters further, hybridization between these species is recorded in a number of zones where their distributions overlap, and this continues to contribute to the problems of defining species limits. Initial taxonomic classification was based exclusively on the analysis of plumage characteristics, but subsequent attempts relied more on behavioural characters and, sometimes, on systems of communication.

These three largely allopatric Eurasian shrikes form a super-species of undoubtedly related taxa. They also share a long common “capricious” taxonomic history, as K. H. Voous put it in 1979, when speaking of the Isabelline Shrike. The complicated taxonomy of this group is demonstrated by the fact that various authorities have treated these taxa as representing one, two, three and even four different species. Several points arise. First, the Brown Shrike is phenotypically well distinguished from the Red-backed Shrike and appears to be a valid species; the breeding ranges of the two overlap in a wide area, and these shrikes may occur in the same habitats and sometimes in neighbouring territories, but only two hybrid specimens are known. A long zone of sympatry exists also between the Brown and Isabelline Shrikes, but the two species generally prefer different types of habitat; only one possible hybrid has been described. Second, the Red-backed and Isabelline Shrikes can be regarded as distinct biological species, although this is a more controversial situation, as the degree of reproductive isolation between these two is still relatively low; mixed pairs and hybrids occur regularly in the small zones of range overlap. Third, the recent suggestion that the western subspecies *phoenicuroides* and the nominate race of the Isabelline Shrike should be treated as constituting a separate species, the so-called “Turkestan Shrike”, merits serious consideration. The conclusions reached by Russian ornithologists are based on vast field experience, and cover morphological considerations, as well as observations concerning behaviour and voice. The current thinking, based on various forms of evidence, is that, within this superspecies, the Red-backed and Isabelline

Shrikes are more closely related to each other, while the Brown Shrike is a slightly more distant relative. Their systematic status is further complicated by the fact that all three are polytypic, the Red-backed Shrike with three subspecies and the Brown and Isabelline Shrikes each with four.

A good example of this confusion is provided by the taxonomy of the Isabelline Shrike. Although in the past frequently lumped with the Brown and the Red-backed, in recent times the Isabelline has normally been treated as a separate species, two of its subspecies breeding in Central Asia and migrating south-west to non-breeding quarters in Arabia and north-east Africa, and the other two breeding in north China and being shorter-distance migrants, wintering in Pakistan and north-west India, west to Iran and Iraq. Now, the type specimen of the species was collected on the non-breeding grounds in western Arabia, and described in 1833, but in 2000 D. J. Pearson suggested that the nomenclature of the species might have become transposed. Subsequent examination of the type specimen at the Berlin Museum has confirmed that the plumage of this bird was actually that of the form hitherto known as “*speculigerus*”, freshly moulted and like those individuals of the species that overwinter in the Nile Valley of Sudan. Consequently, following the Principle of Priority in zoological nomenclature, the taxon previously known as *L. isabellinus speculigerus* must now be treated as the nominate form, *L. isabellinus isabellinus*, while the form previously treated as the nominate takes the next oldest available name, *arenarius*; the name *speculigerus* becomes merely a synonym of *isabellinus*. The nominate race of the Isabelline Shrike is rather warm-toned both above and below, adults having a complete mask and blackish wings. The subspecies *phoenicuroides*, breeding from southern Kazakhstan south to Iran and Afghanistan, is darker above, with a rufous crown, and whiter below, and usually has a bolder white supercilium and white at the base of the primaries; the adult male has a complete black mask, and the adult female has paler lores and, below, strong dark brown chevrons on a whitish background. Males in south Kazakhstan lack rufous on the crown, and this population has been described as *karelini*, but these individuals are otherwise no different from others of the subspecies *phoenicuroides* and do not warrant recognition as a separate race. Compared with first-winter individuals of the nominate race, those of *phoenicuroides* tend to be darker above

Shrikes are compact, well proportioned birds with elongated tails and sturdy legs. One of their signature traits is a robust, hook-tipped bill, an adaptation to a predatory lifestyle. This feature, in combination with a patient demeanour and an upright stance, often gives them the air of miniature raptors. The largest genus in the family is *Lanius*, which contains 27 species in the current taxonomic treatment. Some of these are rather uniform brown or fawn coloured, including the male **Isabelline Shrike**.

This is one of several shrikes for which species limits are disputed, and which may be split in future into two or more species.

[*Lanius isabellinus*,
Oman.

and whiter with stronger and darker chevrons below, and are closer in appearance to juvenile Red-backed Shrikes than are young of the nominate race. The form which breeds in the Tarim Basin of north-west China, previously known as *L. i. isabellinus* but now renamed *L. i. arenarius*, is pale and "washed out", having pale lores and a pale rufous tail not darkening at the tip, the white primary patch tiny or lacking altogether, and a short primary projection with often five tips visible beyond the tertials; the adult male has mid-brown wings paler than those of the two aforementioned subspecies, a pale orangey tail, and pale buff underparts very faintly barred. First-winter *arenarius* is even paler than the adult, pale buffy brown above and washed buff below, with a pale rufous tail not darker towards the tip; it probably never has white at the base of the primaries. The fourth subspecies, *tsaidamensis*, breeds in the Qaidam Depression, in north-central China; it is very similar to the nominate race and may be better merged with it.

Another group of apparently closely related species contains the Long-tailed, the Grey-backed (*Lanius tephronotus*) and the Mountain Shrikes (*Lanius validirostris*), although the taxonomy of these is still not clear. Early researchers recognized just two species, the Long-tailed Shrike, with twelve subspecies, and the Mountain Shrike, confined to the Philippines, with four. Only later was the validity of a third species recognized. Recent observations confirm that the Grey-backed Shrike, a high-elevation form sometimes known as the "Tibetan Shrike", overlaps widely in range with the Long-tailed Shrike without interbreeding with it. Its subspecies *lahulensis*, confined to northern India, is, however, a puzzling bird, appearing morphologically intermediate between the nominate race of the Grey-backed Shrike and the subspecies *erythronotus* of the Long-tailed Shrike. It may represent a stabilized hybrid population. The Mountain Shrike is phenotypically close to the Grey-backed Shrike but smaller, and with a thicker bill. As its English name suggests, it, too, is a mountain species. These last two shrikes, because of their similarities, are sometimes treated as a single species, and their relationship merits further consideration.

In the Afrotropics, the Common Fiscal is widespread in suitable habitats, whereas the Uhehe Fiscal (*Lanius marwiti*) is confined to highlands from north-east to south-central Tanzania, and the very rare Newton's Fiscal occurs only on São Tomé, in the Gulf of Guinea. The taxonomic status of the latter two is controversial. Both have sometimes been regarded as races of the Common Fiscal, as they were, for instance, by C. M. N. White in 1962. A. L. Rand, in 1960, gave species status only to *newtoni*, and this view is reinforced by recent observations, which confirm the existence of rather marked plumage differences, as well as ecological differences, between the Common Fiscal and Newton's Fiscal. The form *marwiti*, elevated to species level by such authorities as B. P. Hall and R. E. Moreau, shows less obvious differences from the Common Fiscal. Indeed, R. J. Dowsett and F. Dowsett-Lemaire had no doubt that it was just a race of the latter, and pointed out that the white eyebrow, so striking a feature of *marwiti*, occasionally appears also in the Common Fiscal population living on the Nyika Plateau, in Malawi. Nevertheless, the Uhehe Fiscal is commonly treated as a full species, distinct from the Common Fiscal, mainly on ecological grounds. Further proposals concerning the already complicated taxonomy of the Common Fiscal include the suggestion that the northern populations, those north of approximately 5° S, may represent a different species from those south of this latitude; this hypothesis, still to be firmly tested, is based on differences in the degree of sexual plumage dimorphism and, above all, on differences in visual and vocal displays.

The most recent taxonomic split within the Laniidae involved the Great Grey Shrike. French researchers presented compelling evidence that the Mediterranean parapatric population did not associate with the "northern" Great Grey Shrike. Their data illustrated that southern populations, given the name of Southern Grey Shrike, differ morphologically and in habitat preferences, and no hybridization between the two forms is known.

The Great Grey Shrike, the Southern Grey Shrike and the exclusively North American Loggerhead Shrike are undoubtedly closely related species. The little-studied Chinese Grey Shrike

(*Lanius sphenocercus*), although more distantly related, could also be attached to this group, the members of which form a superspecies. The first two of these species have frequently been treated as conspecific, but they exhibit a number of features which differentiate them. The Great Grey Shrike tends to be slightly the larger of the two, and has more rounded wings, a less graduated tail with broader rectrices, and slightly shorter legs, and the nominate race, at least, exhibits, comparatively more distinct sexual dimorphism, males having more white in the plumage. Some races, particularly the nominate and, even more so, *homeyeri*, often possess an extended wingbar, whereby the white at the base of the primaries continues onto both webs of the secondaries. Juveniles have barred underparts, and barring can still be present on adults of some subspecies, including the nominate; indeed, it is quite regular on adults of the dark races *funereus* and *mollis*. The Great Grey Shrike is predominantly a taiga species, but one which has adapted also to semi-open grassy agricultural land dotted with copses and hedges; it lives in rather large territories covering 30–100 ha or more, feeds mainly on insects and small vertebrates, particularly voles (Microtinae), and in central Europe nests at an average height of about 8 m. The Southern Grey Shrike has the white wing patch generally confined to the base of the primaries; although some subspecies, *elegans* and *lahtora* for instance, have some white on the secondaries, this is only on the inner webs. Adults of this species never have barred underparts, but faint vermiculations may sometimes be present on juveniles of the nominate race and of *koenigi*. The Southern Grey Shrike is mainly an Afro-Asian species living in warm areas such as scrubland, steppes and deserts; its territory size is generally small, 5–15 ha, and the diet consists primarily of insects but with some small vertebrates, above all lizards. The nest-site may reflect an ecological difference from the Great Grey Shrike, as the nest is generally placed at a height of only 1–2 m in a bush or small tree. The breeding ranges of these two species almost come into contact in southern France; they may even have overlapped at some time in the Aquitaine region, but the data are thus far inconclusive. More interestingly, a proven zone of sympatry exists near the eastern end of the respective breeding ranges, in Mongolia. There, the subspecies *mollis* of the Great Grey Shrike occupies open mountain forest from the base of the slopes to the alpine zone, whereas the subspecies *pallidirostris* of the South-

Like several congeners, the **Long-tailed Fiscal** is essentially piebald, with a dark upperside and bare parts, and a gleaming white underside. In addition to the obviously raptorial bill and feet, all shrikes have several more inconspicuous traits that equip them for hunting. Their eyes protrude slightly and are angled forwards, a little more like a hawk than a typical passerine. This facilitates binocular vision and is presumably an adaptation for hunting. Likewise, they share with birds of prey a large distal digital pad on the toes, and the trick of incapacitating vertebrate prey by dislocating the caudal vertebrae.

[*Lanius cabanisi*,

Most shrikes lack bright colours, but they remain attractive because their plumage is crisply patterned, often with bold blocks of white, grey and black. These simple shades typify a clade of larger species centred on the **Great Grey Shrike**.

White flashes on wings and tail come as standard. They are usually formed by white patches on the bases of primaries and the fringes or tips of the outer rectrices, and they are particularly conspicuous in flight, as shown here. It is possible that they function as visual signals for communicating identity or individual quality to conspecifics, but this remains to be confirmed.

ern Grey Shrike, often known as the “Steppe Grey Shrike”, is confined to the caragana steppe. This spatial and ecological segregation is not, however, very strict, and pairs of *mollis* can sometimes be found in typical *pallidirostris* habitat, although no mixed pairs have so far been found. As with the nominate races of the two species in south-west France, *mollis* and *pallidirostris* exhibit sharp differences in their general appearance.

Recent molecular-genetic studies involving base sequencing of the cytochrome *b* gene indicate that the Great Grey Shrike and the Southern Grey Shrike are, indeed, separate species. The divergence between them is almost as great as that between the Great Grey Shrike and the Loggerhead Shrike. Interestingly, the Southern Grey Shrike seems to be closer to the latter species than it is to the Great Grey Shrike, although this possibility requires further research. Perhaps surprisingly, biometric differences between the Great Grey and Southern Grey Shrikes are poorly described. Spanish researchers have attempted to ascertain sex and age-related variations in external measurements for the nominate race of the Southern Grey Shrike in northern Spain, where they ringed and measured a total of 174 Southern Grey Shrikes and used molecular techniques to determine the sex of each one. They found significant differences in size between the sexes and also between age-classes; adult males were the largest and yearling females the smallest. In terms of biometry, at least, the Southern Grey Shrike is more similar to the Loggerhead Shrike than it is to the Great Grey Shrike. An attempt was made to differentiate Spanish Southern Grey Shrike populations by using tandem repeats in mitochondrial DNA (mtDNA). Four populations, three from the Navarra region, in north Spain, and one from Cáceres, farther south, were sampled and an analysis carried out, the results of which suggested the existence of a genetic flow between populations.

One of the most studied laniid species in recent genetic investigations is the Loggerhead Shrike. There is a mass of literature on the delimitations of the different subspecies, the geographical breeding boundaries and the wintering grounds. To date, however, most of the subspecies described, and their distributions, remain vague, the taxa being hard to identify in the field. In a molecular-genetic study of Loggerhead Shrikes in central and eastern North America, M. Vallianatos and colleagues used a total of 206 samples from 27 populations covering the ranges of three recognized subspecies, namely the nominate race, *migrans* and *excubitorides*, and included sites within a putative zone of intergradation between two subspecies; *migrans* samples were derived both from extant populations and from museum specimens spanning approximately 130 years. For all samples com-

bined, 267 base pairs of mitochondrial control-region sequence were obtained and a total of 23 distinct haplotypes (sets of polymorphic alleles on the same chromosome) identified. The results of analyses suggested that statistically significant differences existed between eastern and western populations of *migrans*, and that there was a higher genetic diversity in the intergrade zone. The authors, whose research was prompted by conservation considerations, identified four “management units” for these eastern and central populations of Loggerhead Shrikes. In a continuation of this study, the researchers used data on mitochondrial DNA sequences in order to explore historical, ecological and geographical factors that might have played a role in the genetic differentiation of these four units, and examined the evidence for intergradation between the subspecies *migrans* and *excubitorides*. No geographically discrete, monophyletic clades were evident, but the distribution of haplotypes indicated some phylogeographical structure that might perhaps reflect an intermediate stage of differentiation between parapatry and reciprocal monophyly. The *migrans*-*excubitorides* contact zone is supported by the mixing of haplotypes unique to each of the hybridizing populations and intermediate frequencies of common haplotypes. The researchers considered that these patterns were a result of the impact of both glacial refugial dynamics and anthropogenic habitat changes in eastern North America.

Scientists who studied the Loggerhead Shrike’s endangered subspecies *mearnsi*, which is confined to the island of San Clemente, in the Channel Islands, off southern California, found that this taxon probably has a small effective population size and that there is insignificant gene flow from the adjacent mainland. The team further used polymorphic nuclear microsatellite loci to characterize genetic variation in contemporary and historic populations of the San Clemente Loggerhead Shrike, and also compared the population with two contemporary populations of the still abundant subspecies *gambeli* living 120 km away on the adjacent mainland. The current population of *mearnsi* has 60% of the genetic variation of the mainland shrike populations and is strongly differentiated from them. Comparison of live individuals with 19 specimens collected in 1915 reveals that most of the variation within the island population was lost before the recent 90% decline in its numbers, and the 20% decrease in variation during the twentieth century is probably attributable to genetic drift. Additional analyses, involving mitochondrial DNA control-region sequences from 80-year-old specimens, show that *mearnsi* may have recently experienced limited introgression from another island subspecies, *anthonyi*, found in the northern Channel Islands of California. Today, gene flow between *mearnsi* and

The **Common Fiscal** is one of several polytypic shrikes with distinctive races. In South Africa, for example, much of the country is occupied by the nominate race with a largely black head, while arid portions of the north and west are occupied by the race *subcoronatus*, which is distinguished by a conspicuous white supercilium. Despite this obvious visual difference, these forms are otherwise very similar and hybridize regularly where they come into contact.

[Left: *Lanius collaris collaris*, Midmar Nature Reserve, KwaZulu-Natal, South Africa. Photo: HPH Photography/Photo Access]

Right: *Lanius collaris subcoronatus*, Kruger National Park, South Africa. Photo: Terry Carew/Photo Access]

mainland *gambeli* is very low, even though a few individuals of the latter visit the island annually. The researchers concluded that the island subspecies population has evolved sufficient genetic independence to justify ongoing conservation efforts designed to counter demographic collapse and genetic erosion; the study, based on DNA amplified from feathers, also demonstrated that it is now possible to monitor the progress of genetic erosion non-invasively. Another study, however, came to a different conclusion. Nine morphological characters of 167 post-juvenile museum specimens were examined in order to ascertain whether Loggerhead Shrikes on San Clemente are diagnosable as *mearnsi*. Four recent specimens from the island were compared with historical specimens, for which exercise a bivariate scatter plot and a discriminant function were used. The few recent specimens were not diagnosable as *mearnsi*, but appeared, instead, to be intergrades between that race and the northern Channel Island subspecies *anthonyi*, being perhaps closer to pure *anthonyi*. The evidence suggests that the shrikes currently on San Clemente are the product of the genetic "swamping" of *mearnsi* by *anthonyi* and that the former is probably no longer a diagnosable taxon. The researchers concluded, however, that the entire Channel Islands population of the Loggerhead Shrike should be protected, as the species has declined drastically throughout the islands.

The San Clemente Loggerhead Shrike Rescue Team also investigated mtDNA sequence variation in five populations, representing four subspecies, including *mearnsi*. Variability was extremely low, and defined four haplotypes. Strong structure was apparent among all three southern Californian subspecies, one haplotype predominating in each respective subspecies. Although potential levels of gene flow between *mearnsi* and neighbouring populations would seem to be low, mtDNA data support field observations that some shrikes visit the island during the winter but do not stay to breed, suggesting that these birds come from the mainland. The similarity in haplotypes between populations from Saskatchewan, in Canada, and those in southern California suggests that a postglacial northward range expansion of the species took place. The results indicated the evolutionary distinctiveness of *mearnsi* and, in contrast to the aforementioned study, justify the continuing efforts for its conservation. This was further substantiated when the team studied the Loggerhead Shrike breeding populations on seven of the eight Californian Channel

Islands. One of the two subspecies, *anthonyi*, is considered to breed on six of the islands, while *mearnsi* is endemic on San Clemente Island. Previous studies had indicated that the San Clemente Loggerhead Shrike is well differentiated genetically from both *anthonyi* and mainland populations, despite the fact that individuals from outside the population are regular visitors to the island. Those studies, however, did not include a comparison between San Clemente shrikes and the breeding population on Santa Catalina, the island closest to San Clemente. The team used mitochondrial control-region sequences and nuclear microsatellites to investigate the population structure of Loggerhead Shrikes in the Channel Islands. They further confirmed the genetic distinctiveness of the San Clemente Loggerhead Shrike, and identified the presence and inferred the source of the non-breeding visitors. The results indicated that Loggerhead Shrikes in the Channel Islands area of south California comprise three distinct genetic clusters, one inhabiting San Clemente Island, another on Santa Catalina Island, and the third breeding in the northern Channel Islands and on the nearby mainland. These findings do not support the suggestion that, for conservation purposes, all Channel Island Loggerhead Shrikes should be managed as a single entity.

Finally, it has been suggested that the most plausible indication of a double invasion of the New World by a Palearctic avian stock is provided by the shrikes. The two North American laniid species are almost certainly derived from two incursions of the same stock, the details of which are believed to have been as follows. An initial immigration took place prior to the Pleistocene glaciations by birds belonging to the widespread Old World species now referred to as the Great Grey Shrike. With the advent of glaciations, this species moved south. As indicated by the extensive Old World range of the Great Grey Shrike, this is a highly adaptable bird, and therefore, with the retreat of the ice, populations in America were able to remain as far south as southern Mexico, while northern populations reoccupied an area extending to central Canada. At some later time, the Great Grey Shrike again crossed the Bering Strait and quickly spread through the boreal region of North America. This second wave of immigrants is currently regarded as having evolved into two subspecies of the Great Grey Shrike, closely related to the Old World races through the Siberian population. The descendants of the

first invasion, however, exhibit certain well-marked differences from the ancestor, differences which have evolved in geographical isolation in these earlier and more southerly populations, and are now regarded as a separate species, the Loggerhead Shrike. Members of the latter species resemble some of the ecologically parallel populations of the Old World species, and during the breeding season in North America they do not overlap in range with the Great Grey Shrike, which is generally known on that continent as the "Northern Shrike".

Morphological Aspects

Probably the best-known characteristic of the laniids, the one most closely associated with this family, is the bill. This is short, strong and sharp, and hooked at the tip, and has a tomial "tooth" in the upper mandible and a corresponding notch in the lower mandible. This tomial tooth is very similar to that possessed by the falcons (Falconidae) and was one of the reasons why shrikes were associated taxonomically with raptors in early classifications. They are similar to raptors also in many other morphological and behavioural aspects. Examples are the slightly protruding position of the eyes, which facilitates binocular vision, the large distal digital pads on the toes, and the technique of killing vertebrate prey by dislocating the caudal vertebrae; further similarities include their hunting methods, which include perching, hovering and flushing, the mantling of captured prey, the repeated use of favourite perching sites, and the regurgitation of pellets. Shrikes differ from raptors in that they capture and kill their prey with the beak, rather than with the feet, and they store food items in a cache, and not in the crop. In addition, they impale each prey item or secure it in a suitable crack or crevice before dismembering it, whereas falcons use the feet in order to hold down the food and then tear it apart.

The Laniidae range in size from 14 cm to 50 cm and weigh from 14.5 g to 100 g on the breeding grounds. Besides the distinctive bill, described above, they have a stout tarsus which is regularly scutellated on the outer posterior surface. The basal joints of the middle and outer toes are united, and the claws are strongly curved and rather sharp. Typically, the plumage combines white, grey, black, and brown or reddish-brown. One of the most brightly coloured *Lanius* shrikes is the east Himalayan subspecies *tricolor* of the Long-tailed Shrike, which sports a black cap and mainly deep rufous upperparts. With one exception, all members of the family have a dark mask that stretches from the

bill and forehead, across the eye, and backwards to the cheek or nape region. The exception is the Magpie Shrike, which is almost wholly black.

Shrikes of the genus *Lanius* are small to relatively large birds. The smallest is the Central African Emin's Shrike (*Lanius gubernator*), and the largest and heaviest is the high-elevation race *giganteus* of the Chinese Grey Shrike. Males and females are often quite similar, sexual dimorphism being very obvious in only a few species and particularly in the Red-backed Shrike. All juveniles are typically brown or brownish-grey and heavily vermiculated.

Loggerhead Shrikes exhibit little sexual dimorphism, although females may be slightly smaller than males and have browner primaries than the latter. It has been suggested that females also have a significantly higher ratio of wing chord to tail length, and that this could be used as part of an equation to differentiate the sexes with 77.4% accuracy. A Canadian study of intraspecific variation and sexual dimorphism among Loggerhead Shrikes, however, concluded that significant variation in this ratio within populations makes its employment in correctly identifying subspecies of Loggerhead Shrike untenable.

The two *Corvinella* species are large and noticeably long-tailed. The Yellow-billed Shrike has a length of 30–32 cm, of which 16–18.5 cm is accounted for by the tail; with its brown, vermiculated plumage, it resembles a giant juvenile *Lanius* shrike. The Magpie Shrike measures 34.5–50 cm, 22.5–35 cm of which is the tail, and is almost completely black, with white scapulars and wing patches.

The two white-crowned shrikes in the genus *Eurocephalus* are large, stocky laniids with a proportionately shorter tail than that of other members of the family. They have a length of 19–24 cm and a weight in the range 42–70 g, the Southern White-crowned Shrike being slightly the larger of the two. Adults of both are distinguished by the white crown and nape, contrasting with the black facial mask. They have brownish upperparts and a pale throat and underparts, the Northern White-crowned being further distinguished by its white rump, which is striking in flight.

The black mask possessed by shrikes is thought to have a function of absorbing light in the head region, especially around the eye, thus preventing its reflection into the eyes, which, if it occurred, could reduce the sharpness of the image. Shrikes often face into the sun when foraging. It has been suggested that this confers the advantage that the prey is more noticeable because its shadow is cast towards the perched shrike, providing a larger

Another group of species in the genus *Lanius* is characterized by patches of rich rufous colour, as found in the **Tiger Shrike**.

Sexual dichromatism in this group is quite dramatic, with the male being sharply patterned and richly coloured, while the female is a relatively muted, barred version of the male. The black mask is striking in the male, set against a pearly white throat and a dove-grey crown and nape. In the female, however, the same head pattern is smudged and ill defined.

In many shrike species, for example the **Grey-backed Shrike**, adults of both sexes are very similar but juvenile plumage is usually distinctive. In this case, both adults have the classic black mask, wings and tail, along with grey upperparts, whitish underparts, and a delicate peach wash on the flanks. The juvenile (right) is much duller and browner, with an indistinct head pattern, faint barring on the underside and a horn-coloured lower mandible, all features that are typical of juvenile shrikes.

[*Lanius tephronotus tephronotus*.]

image for detection; it is advantageous also because the attacking shrike approaches with the sun in front of it, so that its shadow does not give away its approach and prompt the prey to escape. It has been suggested further that the pale belly of the shrike makes it less visible against the background of the sky.

Aberrantly pale, leucistic, shrikes, as well as dark, melanistic, individuals, are occasionally reported. Such cases have been documented for the Common Fiscal, the Red-backed, Brown, Woodchat, Great Grey, Long-tailed and Loggerhead Shrikes, and the Yellow-billed and Magpie Shrikes. Plumage coloration appears to be influenced by humidity. This was described for Loggerhead Shrikes in North America and for Southern Grey Shrikes in north Africa; from pale coloration in the deserts, the plumage becomes increasingly darker with increasing humidity, the darkest subspecies inhabiting rainy regions or areas of greater cloudiness.

Males of many bird species display colourful plumage, but there are just as many species, and entire avian genera, that are achromatic, meaning that they have predominantly white, grey and black plumage. Achromatic plumage is a typical feature of many shrikes. In a recent study, scientists examined the black tail spots on the two outermost pairs of tail feathers, T6 and T5, of Lesser Grey Shrikes (*Lanius minor*) and assessed the importance of these as a sex discriminant and as an indicator of individual quality. The results suggest that the black pattern, especially on T5, is important in determining sex, but only in combination with other plumage or morphological features; the presence of black spots on T5 was an indicator also of male age. In terms of breeding performance, however, there was no evidence that the presence of these black spots, and their size and precise pattern, were indicators of individual quality of either sex.

Geographical variation among four Common Fiscal subpopulations along an altitudinal gradient in South Africa was one of several themes studied by S. Soobramoney and colleagues. The researchers found significant variation in 13 morphological features and 38 skeletal characters. Common Fiscals were largest in cooler, more arid areas and smallest in warmer, more humid localities, as would be expected from Bergmann's Rule. Variations in morphology and anatomy exhibited a significant correlation with eleven climatic trends. For example, cardiopulmonary organ mass and blood haematocrit value increased with altitude, reflecting adaptation to low ambient temperatures and decreased oxygen pressure associated with high altitudes. Similarly, Common Fiscals from more mesic habitats at low altitude were found to have a higher basal metabolic rate, evaporative water loss and body temperature

compared with those from semi-arid areas at higher altitude. Clear differences in circadian rhythm of these three parameters were apparent, too, and the fiscals exhibited seasonal acclimatization in thermoregulation, increasing their basal metabolic rate and oxygen consumption in cold conditions, and reducing their body temperature in the winter months.

An interesting question was addressed in Germany, that of whether Red-backed Shrikes are becoming smaller. From 1964 to 1998, a total of 2811 shrikes from a stable population in Baden-Württemberg was trapped. The wing length and body mass were recorded, and two secondary feathers (the 8th and 9th), a greater secondary covert and an outer rectrix were plucked. During this period the mean wing length decreased, the reduction beginning around 1991 in the case of females and in 1995 for males and fledglings. The length of the eighth secondary decreased slightly from 1964 to 1998, while that of S9 increased. There was no change in body mass during this period. The degree of heritability was high until the end of the 1980s, but decreased after that. As morphological characteristics with a high degree of heritability are not closely associated with fitness, there was no significant connection between the measurements and breeding success, or between the measurements and the rate of return to the breeding grounds from non-breeding quarters.

Sedentary shrikes undergo a single complete post-breeding moult annually. Of the migratory species, some partially suspend the moult while on migration and others have two complete annual moults. Most juvenile laniids are known to retain some of their greater primary coverts on the upperwing until the second autumn moult. The presence of these buff-tipped feathers is considered a reliable criterion for the ageing of first-year individuals, both in the hand and in the field.

In a study of moult among Palearctic migrants in Ghana, it was found that first-year Woodchat Shrikes began by replacing primaries P3 or P4 and then moulted their primaries descendantly. The earliest individual in active moult was one trapped on 19th November. By mid-December, all juveniles were replacing their outermost primaries, but none had shed the inner primaries or the secondaries. This corroborated previous studies, which had concluded that first-year shrikes moult only the outer five or six primaries during their first winter. One adult female showed suspended moult on 14th December, when secondaries S4 and S5 had not yet been renewed. The retrapping of moulting individuals indicated that primary scores increased slowly. The Woodchat Shrike, with a comparatively slow moult, did not complete

it any later than the rapidly moulting species because not all of the remiges were replaced. It is suggested that slow moult is to be expected in the winter quarters whenever birds are faced with prolonged and predictable wet seasons, as in southern and central Africa.

The Loggerhead Shrike breeds throughout much of North America, the northernmost populations being migratory. Little is known about the moult of this species and how it may vary geographically, but it appears that different populations follow different moult strategies. G. E. Pérez and K. A. Hobson investigated the moult sequence of 27 breeding Loggerhead Shrikes by using stable-hydrogen-isotope analysis of flight-feathers. As feather isotope varies with the latitude at which the feather is, it is a relatively simple matter to identify those feathers grown at localities south of the shrike's breeding area. For each individual, eleven feathers were sampled in order to determine the locations between the breeding grounds and the wintering grounds where moult took place. Feather samples were taken in central Saskatchewan and in the southern region of the Saskatchewan–Manitoba border, in south Canada. It was found that the shrikes began the moult of the flight-feathers on the breeding grounds, where outer primaries P1 and P3 were replaced, but then largely suspended the moult until they arrived in their wintering areas. According to the isotopic evidence, the first primary appears to provide information on the individual shrike's breeding latitudes, whereas the innermost tertial gives information on its wintering or southernmost moulting latitudes.

In a study of Red-backed Shrikes in south-west Germany, 33% of individuals during the breeding season had a deficient tail. Individuals with several defective rectrices were more frequent in occurrence than would be expected. The central tail feathers were lost more frequently than were the others and were regrown more slowly, and in the period from May to July the shrikes had more feathers missing than they had growing ones. Some of the lost rectrices were replaced late, often during the postnuptial moult of the body feathers. There were no indications of a regular moult of the tail feathers, either by breeding birds or by unmated ones.

The flight-feather moult of Red-backed Shrikes in the non-breeding range was studied by examining data from 302 museum skins, as well as eleven live individuals trapped in sub-Saharan Africa. The majority seem to start the flight-feather moult soon after arrival in their southern African non-breeding quarters. About 75% of individuals had started before mid-December, during the main arrival time of the species. The period between the day when 50% of the population had reached the first stage of recorded moult and the day when they reached the last stage amounted to about 82 days, and nine days later 75% had reached this last stage. For the individual shrike, therefore, moult can be estimated to cover about 80–90 days, with the main moulting period between mid-November and mid-March, thus spanning about four months. There was no apparent difference in timing between males and females.

Avian morphological traits are known to vary with age. For Red-backed Shrikes, a significant difference in wing-chord length between adults and yearlings was found in females but not in males. For Bull-headed Shrikes (*Lanius bucephalus*), no statistically significant differences were detected in the bill dimensions, the total head length and the tarsus length between the two age-classes within each sex. This suggests that, in both sexes, the skeletal parts were fully grown within the first year of life. Furthermore, although adult females had longer wings and a longer tail than those of yearling females, significant differences were not found in males, and the differences between the means were smaller. The similarity between the age-classes of males can be attributed to the moult pattern, because adults undergo a complete post-breeding moult, and some other individuals in post-juvenile moult change all of their feathers except for some primary coverts. The explanation for this has generally focused on the need for wing manoeuvrability as a response to selection pressure such as predation or foraging efficiency; or, alternatively, that the young are constrained by poor nutrition. In a study in Japan, however, it was suggested that the similarity between males of different ages, and the disparity between different-aged females, could be attributed

to sexual selection and to natural selection, respectively. When a male Bull-headed Shrike courts a female, he raises his head and tail upright and moves them from side to side, and during pursuit of a female he exaggerates the white patches on his wings. Selection would therefore dictate that yearling males grow wings and a tail as long as those of adult males in order to attract a mate. This was corroborated by the fact that, on the island of Chichijima, mated adult male Bull-headed Shrikes had a significantly longer tail and wing-chord length than did unmated males.

Because the heart is the body's power source, its relative size indicates its capacity for driving the blood around the body. Studies of Loggerhead Shrikes revealed that this species' heart weight decreases in the colder months of the year; in winter it accounted for 1.26% of the body mass, compared with 1.47% in the summer. Moreover, the average, 1.35%, is greater than that for other bird species of similar size, suggesting that, in comparison with them, the shrikes have a more strenuous way of life.

Habitat

Most species of shrike occupy edge habitats and open areas that consist of mosaics of short grass, bushes, trees and prominent perching sites. Some occur in sparsely vegetated xeric habitats, while others inhabit woodland and forest, usually along edges or in clearings. The distribution of the family stretches from north of the Arctic Circle southwards to the tropics and to the tip of southern Africa.

Laniids are typical birds of semi-open habitats. They require perches offering a good view down of the ground, where most of their prey is taken. Most species have benefited from deforestation and have adapted well to low-intensity farming. A few shrikes, however, are forest-dwellers. The rarest, Newton's Fiscal, is restricted to primary lowland and middle-altitude forest on the island of São Tomé; it has never been recorded in secondary forest or in cultivated areas.

Many shrikes show seasonal differences in habitat preferences. For example, some prefer forest edges, and ecotones between forest and open grassland or agricultural land, as breeding habitat, but during the non-breeding period they have a strong preference for meadows and arable areas.

Loggerhead Shrikes have been particularly well studied with regard to their habitat preferences. They use prairies, pasture,

In another odd echo of a situation found in raptors, a few species of shrike are polymorphic, with rare blackish morphs being particularly regular in some regions. The name fuscatus, for example, was given to dusky birds from south-east China and Hainan, but these turn out to be simply a melanistic form of the Long-tailed Shrike. The evolutionary basis for these (usually male) polymorphisms is unknown.

The genus *Corvinella* contains two anomalous shrikes from sub-Saharan Africa. One of these, the **Yellow-billed Shrike**, differs from *Lanius* shrikes in its longer tail, grizzled brown plumage, and bright yellow bill. It is also considerably more gregarious, breeding co-operatively in groups of up to 25 individuals, and singing duets. In addition, it does not impale prey in the manner of most shrikes. Although this species has been the subject of taxonomic debate over the years, it does appear to be a true shrike, not too far removed from *Lanius* on the basis of cranial morphology and genetics.

sagebrush (*Artemisia*) desert, and fencerows or shelter-belts of agricultural fields, as well as old orchards, riparian areas, open woodland, farmsteads, suburban areas, abandoned railroads, cemeteries, golf courses, and reclaimed strip mines. Scattered shrubs or trees, particularly thick or thorny species, provide nesting sites and hunting perches, and thorny vegetation serves also for impaling prey. In south-west Idaho, impaling stations were located 7–65 m from the nest, contained one or two sharp points, and were well protected within the shrub. Fences, utility wires, and strong-stemmed grasses can also be used as perches. In the upper Midwest, an abundance of open habitat, foraging areas, and elevated perch sites were considered the most important factors in habitat suitability. Grasslands and structurally similar crops, such as alfalfa (*Medicago sativa*) and oat fields, are preferred over row crops, such as corn or soybeans. Of 48 nests in Minnesota, 45% were found in grassland, 37% were adjacent to agricultural fields, and 18% were in pastureland; compared with unoccupied sites, nest-sites had a greater amount of grassland and pasture and longer hedgerows. To the south, in south-western Iowa, nesting areas had more tree cover and bare ground and fewer shrubs than did unoccupied sites, probably reflecting the species' preference for large nesting trees. Again in Iowa, Loggerhead Shrikes nested in roadside areas with smooth brome (*Bromus inermis*) and small, scattered trees and shrubs, whereas most territories in Missouri and Illinois were in pasture.

In Canada, Loggerhead Shrikes breed in pastures with isolated trees and shrubs, thickets or hedgerows, and in thorny bushes alongside railroads. In Ontario and Quebec, they nested in isolated trees more than in hedgerows; hawthorn (*Crataegus*) and red cedar (*Juniperus virginiana*) were the two trees most commonly utilized. In south-east Manitoba, willow (*Salix*) bushes, growing singly or in clumps, and deciduous trees in shelter-belts were the preferred nesting sites; these sites contained more pasture and fewer trees than did randomly selected sites, and also had longer fencerows than found at the latter. Nest trees in pasture had a wider canopy and a larger diameter, and they were surrounded by fewer trees with a height in excess of 2 m; nest trees in cropland were surrounded by fewer shrubs less than 2 m tall. In south-east Alberta, an average of 6.6 breeding pairs was found in seven 41.5 km² blocks containing more than 100 clusters of trees or shrubs, whereas the average in twelve blocks containing fewer

than 50 such clusters was only 2.3 pairs. Compared with random sites, areas within 400 m of localities where shrikes were observed contained a greater diversity of habitats and more frequently encompassed roadside areas, farmyards and shelter-belts; no differences were detected, however, in the proportion of annually cultivated fields, pasture, or hayland in areas around shrike locations. In another Alberta study, breeding habitat of Loggerhead Shrikes had more silver buffaloberry shrubs (*Shepherdia argentea*), a greater percentage of grass more than 20 cm tall,

The **Magpie Shrike** is included in *Corvinella*, although it was once considered sufficiently distinctive to warrant separation in its own genus, *Urolestes*. It is the largest and perhaps the most spectacular member of the shrike family, with an extremely elongated tail, some 22–35 cm long. The plumage is almost entirely black, with striking white patches on the scapulars and primaries, both of which are dramatically conspicuous in flight. It is a widespread specialist of the park-like savanna, semi-dry Acacia scrubland and mopane woodland of East Africa, extending southward from Kenya to South Africa.

The genus *Eurocephalus* was previously treated as a single species, but this has now been split into the Southern White-crowned Shrike (*E. anguitimens*) and the Northern White-crowned Shrike. On the evidence of genetic analyses, both these forms appear to be closely related to classic Lanius shrikes, but they differ from them in a variety of morphological and behavioural traits. For instance, they spend more time on the ground, and they live permanently in closely consorting pairs, or in small groups. They are unique in having a glaring white crown and rump, and differ in the distribution of tarsal scutellation. Overall, they are probably the least "shrikelike" of the shrikes.

and a taller mean height of grass and forbs than did heavily grazed habitat unoccupied by the species.

Throughout the Great Basin shrub-steppe and the Great Plains grasslands of North America, the abundance of Loggerhead Shrikes was positively correlated with the percentages of shrub cover and of bare ground, and with the average height of emergent forbs or shrubs; it was negatively correlated with percentage of grass cover. In Oregon and Nevada shrub-steppe, Loggerhead Shrikes were increasingly more numerous with increasing rockiness, dead vegetation and shrub diversity, and with greater cover of spiny hopsage (*Greyia spinosa*), budsage (*Artemisia spinescens*) and shortspine horsebrush (*Tetradymia spinosa*). In Washington, the species' territories were located in areas characterized by relatively large, thick shrubs interspersed with native bunchgrasses or sand-dune openings with about 40% bare ground. Vegetation types supporting Loggerhead Shrike territories included big sagebrush (*Artemisia tridentata*) in lowland and upland areas, mixed shrub and antelope bitterbrush (*Purshia tridentata*); areas used by these shrikes also had a strong horizontal and vertical structural diversity. Community types not dominated by shrubs, such as grasslands and riparian areas, were shunned. In Idaho shrub-steppe, the shrikes nested in big sagebrush, antelope bitterbrush and greasewood (*Sarcobatus vermiculatus*), but in neighbouring north-central Montana, near the Missouri River, they preferred limber pine (*Pinus flexilis*) and Rocky Mountain juniper (*Juniperus scopulorum*) to big sagebrush. In Washington, the shrub species present more commonly around nest-sites than at unoccupied sites were live big sagebrush, antelope bitterbrush and spiny hopsage, and the less common species were rabbitbrush (*Chrysothamnus nauseosus*) and dead antelope bitterbrush; nesting sites exhibited taller shrubs and a greater shrub canopy, and less annual grass cover, than found at unoccupied sites. Loggerhead Shrikes here preferred to nest in big sagebrush and antelope bitterbrush, and avoided spiny hopsage, rabbitbrush and green rabbitbrush (*Chrysothamnus viscidiflorus*). The shrubs utilized for roosting were large, dense living ones, whereas tall dead shrubs providing good visibility were used as perches.

Canadian researchers employed satellite imagery as a means of assessing breeding-habitat availability for the Loggerhead Shrike in Quebec. They found that, of 1700 plots located in the historical breeding range, 310 fitted the required criteria, sup-

porting a total of 3988 pastures, and they visited more than 500 of these pastures in order to validate their current status. The researchers found that the Outaouais region would be the most suitable for nesting Loggerhead Shrikes in southern Quebec; here, suitable habitat remained because more than two-thirds of the visited sites were still pastureland, hawthorns were well distributed in the region, and pastureland fragmentation was less than elsewhere. The conclusion was that the availability of breeding habitat does not limit the establishment of a breeding population of Loggerhead Shrikes in Quebec, because it is estimated that thousands of hectares of suitable habitat survive in that province.

Modern agriculture contributed to the decline of many bird species in western Europe during the second half of the twentieth century, shrikes in particular having suffered through habitat degradation or loss (see Status and Conservation). The Lesser Grey Shrike is among the most threatened breeding bird species in the region. In France, 50–60 pairs still breed at two sites in the Mediterranean area, where they nest in tall trees, either isolated or in avenues, and, more importantly, appear to depend on vineyards associated with grassy fallows. In one of the two sites, west of Montpellier, a study of the local land use revealed the predominance of vineyards, followed by fallows, and with only minor elements of small orchards and gardens. What seems essential is that vineyards and fallows occur in a mosaic arrangement of small plots. The shrikes capture their prey in both habitats, but mostly in fallows.

The importance of habitat composition and territory size for reproductive success among Lesser Grey Shrikes in Slovakia was investigated. Territory size varied significantly, but did not determine breeding success. Territories contained a high diversity of habitats, meadows being the most important type, but all territories also contained considerable expanses of bare ground. In fact, bare ground was the preferred habitat type at the beginning of the breeding period, whereas, during chick-feeding, mowed meadows were clearly preferred. Access to insect food seems to be the key factor in explaining these preferences. The tree species used for nesting varied considerably between 1996 and 1999, and variation in the development of foliage cover seemed to be the cause of this. Although Lesser Grey Shrikes exhibited a clear preference for some habitat types, the researchers were unable to identify any influence of habitat variables on territory selection and breeding success. It could be that the

study area in general provides optimal conditions for all breeding pairs, and the small differences in territory quality may be negligible.

P. Koskimies found that transmission-line areas in Finland provided a favourable nesting environment for Red-backed Shrikes. The study indicated that the nesting frequency of this species in such areas, in which a significant portion of the total population nested, was considerably higher than it was in other Finnish habitats. The trees and bushes in transmission-line areas

have become vital compensatory habitats following the loss of natural meadows. In a study of Red-backed Shrikes in southern Austria, an objective census technique was devised, enabling relative measures of abundance and habitat cover to be obtained. The shrike's abundance was found to have a positive correlation with grassland grazed by livestock, with fence lines and with scattered trees and shrubs, and a negative one with arable land and ungrazed grassland. Shrikes were most strongly associated with a mixture of grazed grassland and scrub, but their abundance in this habitat increased only when scrub was limited to 10–15% cover.

In Switzerland, ornithologists investigated habitat availability and farming intensity and studied their effects on breeding-bird densities and on habitat use during foraging. It was found that the Red-backed Shrike was influenced most by farming intensity. Shrikes were more widespread and more abundant in areas farmed at low intensity than in more intensively farmed areas, where they utilized areas close to pastureland, dry grassland and hedges, woodlots, orchards and vineyards. The density and height of vegetation were important, meadows being suitable for ground hunting when they were newly cut, while tall grassland was better for catching aerial prey. Foraging sites were much closer to the nest in low-intensity farmland than in intensively farmed areas.

The details reported above are similar to findings for Loggerhead Shrikes in Florida, where the effects of suboptimal substrate on this species' hunting capabilities were observed. Hunting attempts and hunting success before the grassland was mown were not significantly different from those after mowing, although there were significant differences in the number of prey caught in aerial chases and during hovering and in the number captured by perch-hunting. None of the shrikes adjusted the boundaries of its territory following the modifications, but all were apparently able to overcome the effects of tall vegetation by altering their hunting behaviour.

Low grassland appears to be the optimal habitat for Loggerhead Shrikes, as it permits energetically efficient hunting. In addition, it was found that the density of hunting perches affected the nutritional condition of non-breeding territorial Loggerhead Shrikes. Areas of a Florida cattle ranch that lacked shrike territories had only few fences and sparsely scattered trees, and could not therefore be exploited by the shrikes. It was shown that all

*One of the most persistent and distinctive traits of shrikes is their habit of sitting conspicuously on prominent perches, quite often the highest one available. This behaviour, like the hooked bill, is related to their ecological role as sit-and-wait predators. It also makes shrikes popular with birdwatchers because they are fairly easy to find and to observe for prolonged periods. After patiently scanning for prey, this **Common Fiscal** is taking a break from foraging for a bout of preening. Shrikes preen, like all other birds, to minimize their parasite load and to maintain the immaculate quality of their plumage.*

[*Lanius collaris collaris*,
Hermanus, South Africa.
Photo: Jaime Rojo]

*In the temperate zone, most shrikes are solitary birds. Even paired individuals usually forage separately, a habit that presumably helps to reduce competition for scarce food resources. In the tropics, however, some shrikes are highly social. The **Northern White-crowned Shrike**, for example, generally lives in small groups which defend shared territories and often forage together. A tropical insectivore presumably encounters more prey, and more predators, than a temperate insectivore. On the one hand, the abundance of prey may allow several individuals to hunt in close proximity, thus reducing the costs of living in a group. On the other hand, the greater risk of predation might also increase the benefits of sociality.*

territories comprised a logical mosaic and had the same amount of utilizable area; that large territories contained more "dead" space; that the ratio of benefits to cost in terms of energetics varied with territory size; and that a shrike's nutritional condition, as determined by feather growth rates (ptilochronology) varied inversely with territory size. Similarly, shrikes inhabiting pastures were in better nutritional condition than those with territories in citrus groves, where application of pesticides had an adverse effect on the prey base. The condition and the breeding success of Loggerhead Shrikes living on cattle pastures were likewise adversely affected when a common fertilizer, sodium ammonium nitrate, was sprayed on the pasture; seven eggs, two nestlings and eight fledglings disappeared, or died from causes attributed to the spraying, in addition to which one male and seven females disappeared and one territory was abandoned. Shrikes are considered good indicators of habitat quality, and these observations suggest that further studies are required in order to examine the effects of supposedly "environmentally friendly" fertilizers.

Common Fiscals are resident in South Africa, where their territories, varying in size from 0.3 ha to 6.3 ha, are located in both natural and human-modified habitats. The availability of hunting perches had an important effect on habitat selection by this species, which was found to avoid open land used for monoculture crops, as well as heavily wooded regions. Common Fiscals were able to colonize areas having no natural perches by making use of overhead cables, fence lines and artificial perches. The Common Fiscal is unusual among shrikes in that it appears not to be following the current global trend of decline recorded for many other laniids (see Status and Conservation). A population in South Africa inhabiting natural habitat, in the form of savanna, and human-modified habitat, represented by eucalypt (*Eucalyptus*) groves and monoculture grasslands, was studied in order to determine whether foraging behaviour could be contributing to their population stability. The three habitats differed significantly in the perch structures and perch heights that they provided, and the fiscals adjusted both their search height and their foraging method accordingly, performing more aerial hunting from tall eucalypt perches and fewer from lower fence lines in grassland. Territories were smallest in eucalypt groves, where the fiscals spent less time in flying between perches. Hunting

success and prey size did not differ from one habitat to another, but capture frequency was greatest in human-modified habitats. Common Fiscals are uncommon in many protected natural areas in South Africa, but their flexibility in foraging methods has allowed them to exploit new habitats, and they have increased their range and numbers in modified habitats.

Again in South Africa, a comparative study of the numbers of Red-backed Shrikes in different habitats on the wintering grounds showed that the highest densities, of 10–15 individuals per 10 ha, were recorded in semi-arid parts of the former Transvaal Province. Highest numbers were in arid savanna of medium cover and height. A comparison with the densities in the best breeding areas in Europe reveals a similar number of full-grown individuals to that present in the arid savannas in southern Africa. Understanding the winter distributions of migrant birds is important, because productivity and recruitment are influenced by conditions at several places and at different periods in the life cycle of individuals (see Movements).

Habitat selection by migratory populations of two sympatric shrike species, the Bull-headed and Brown Shrikes, was examined in northern Japan between 1992 and 1997. While Bull-headed Shrikes did not show any particular preferences, Brown Shrikes bred mainly in natural grassland with shrubs. Since available habitat for Brown Shrikes has decreased rapidly in and near the study area, this species' strong tendency to return to the same breeding sites each year may be the result of a scarcity of habitat. Bull-headed Shrikes, on the other hand, may have a higher tendency to disperse because they are habitat generalists. With its more narrow requirements, the Brown Shrike appears to have suffered significantly from habitat loss, while the Bull-headed Shrike has not been adversely affected.

The way in which habitat use and perch selection by Great Grey Shrikes were influenced by prey type and the presence of a snow layer was investigated in south-west Finland. It was found that the habitat chosen depended on snow cover, reflecting a preference for poorly vegetated arable fields when hunting invertebrates and for vegetation-rich habitats when available prey were mainly vertebrates. As is consistent with theories on optimal perch height, the shrikes, when hunting mainly vertebrates, chose higher perches and also increased the time spent on each perch, probably because vertebrate prey are less frequent than invertebrate

Most shrikes sing alone to attract mates, but the gregarious species will often defend their shared permanent territories by singing together. The **Grey-backed Fiscal**, for example, lives in groups of up to 20 individuals, each of which forages alone unless drawn to a locally abundant resource, such as ant swarms or termite hatchings. When the territory is threatened by an intruder, however, several individuals may gather on a prominent perch to display communally. This spectacle includes a co-ordinated chorus, the purpose of which is presumably to deter rivals by signalling territory ownership and group quality.

[*Lanius excubitorius*,
Lake Naivasha, Kenya.
Photo: Hanne & Jens
Eriksen]

prey. A selection of lower perches when hunting invertebrates was evident in mild winter periods, but not in the autumn. Snow cover increased the average distance to mammalian prey captured, but the average frequency of mammal capture remained unchanged. The shrikes preferred to hunt invertebrates when these were available, rather than to adopt a hunting strategy that would optimize the encounter rate with vertebrates. The rate at which they hunted ground-living prey decreased, however, as the snow depth increased, whereas energetically costly types of hunting behaviour remained unchanged.

In Navarra, in northern Spain, it was found that the geographical distribution of the Red-backed Shrike is linked with a combination of both the vegetation available for nesting and the climate. This allows the shrikes to be used as bio-indicators of the climate and vegetation in given areas.

General Habits

Most migratory species of laniid hold all-inclusive territories on the breeding grounds, and guard smaller feeding territories when on migration or in the wintering quarters. They make use of exposed sites for perching, when they usually adopt an upright stance, except when watching prey below them, or crouching if a larger predator is in the vicinity. When moving to another perch, they typically drop down and fly close to the ground with bursts of rapid wingbeats, swooping upwards at a steep angle to alight on the next perch. It appears that the upright stance serves to advertise their presence, and the exposed perch facilitates the sit-and-wait foraging technique. They scan the area surrounding their prominent perch and swoop down to capture prey, which they detect, probably, by its movement. Foliage-gleaning and aerial capture are not frequently undertaken, even though they may be the only means of gathering food in some situations, as when the undergrowth is especially tall during the rainy season and the sedentary individual will not abandon its territory. In such cases, shrikes will resort to hawking insects or other birds, snatching them in mid-air, and to hovering, both of which are energetically the most expensive modes of flight and hence the least preferred.

Members of the two African genera *Eurocephalus* and *Corvinella* are gregarious, and often occur in groups. Both genera are thought to be co-operative breeders. Two other African shrikes are likewise gregarious: the Long-tailed Fiscal (*Lanius cabanisi*); and the Grey-backed Fiscal (*Lanius excubitorius*). The latter, and possibly also the former, breed co-operatively, with one breeding pair that benefits from the presence of a varying number of helpers (see Breeding). All the other species are found singly or in solitary pairs, although they sometimes form loose colonies, particularly in the case of the Lesser Grey Shrike, and concentrations can be encountered also during migration.

Shrikes are also highly territorial, the territories of the small Red-backed Shrike extending over an average of 1.5 ha and those of the much larger Great Grey Shrike covering up to 100 ha or more. Establishment of territories is a complicated process, especially when two sympatric species return at different times from the wintering grounds. An example of such a situation is found in Japan, where the Bull-headed Shrikes return early in the breeding season and begin to set up territories. On the arrival of Brown Shrikes, however, competition for breeding territories becomes intense, and the territories held in the previous year have to be re-established in the face of the pressure exerted by interspecific and intraspecific competition. It appears that this situation leads to the depression of populations of both species in a given area, because the number of territories that can be accommodated is limited and depends on the carrying capacity of the habitat.

Territoriality is a feature also of transient and winter resident Brown Shrikes in Taiwan. Large numbers of these crowd into the available habitat during the passage period, and the cost of maintaining territories changes markedly, depending on the number of shrikes present. Almost a quarter of the autumn passage migrants arrive before the wintering shrikes, while almost three-quarters of wintering Brown Shrikes arrive in Taiwan during the period of the species' autumn passage through the island. Studies revealed that the frequency of intraspecific aggression was correlated with the number of individual shrikes seen along a transect line. Among ringed individuals that returned during passage time, 80% returned directly to their previous territories, but some waited for the departure of passage migrants before establishing territories. Departure from and arrival at the study area were frequent during the winter months, but no individuals moved territories within the study area. On average, 25% of ringed overwintering shrikes returned to the study site in subsequent years, whereas no passage migrants were recorded as doing so.

Perch sites are important in territorial behaviour, and influence the life-history traits of shrikes. At the Kenting National Park, in southern Taiwan, the foraging behaviour, perch choice and use, and interspecific and intraspecific interactions of migratory Brown Shrikes were observed. It was found that the shrikes had an overwhelming preference for perching on protruding branches on a side of the tree canopy, which made it easier for them to detect prey on the ground and to keep an eye open for raptors. They also rested a lot between hunting bouts while on migration, when their hunting rate was very different from that during the breeding season. Of a total of 89 aggressive interactions with other individuals, 62 involved conspecifics and 27 were with members of other species. Of the 62 intraspecific interactions, three were with groups of up to five migrating Brown Shrikes that landed in the study plot before heading out to sea, presumably towards the Philippines. It appears that Brown Shrikes in Taiwan maintain feeding territories while on migration.

Shrikes require two types of perch. Being diurnal hunters, they need daytime foraging perches, which they utilize also both for dismembering prey and for perching conspicuously in order to advertise the territory to intruding conspecifics. In addition, they require nocturnal perches for the purpose of roosting. Both types of perch are used repeatedly by individual shrikes. From the few data available on the selection of night roosts, it seems that these are generally situated above ground level in tall, dense, live shrubs, screened by overhanging limbs, and often marked by large areas of faecal deposits, or "whitewash", and have regurgitated pellets strewn around them. The adults have been observed to reach the roost about one hour after sunset and to leave about 40 minutes before sunrise. When the young are still in the

Most shrikes produce a variety of tuneless, grating calls, a common variant being "schach". Indeed, the word "shrike" is thought to be derived from these harsh notes, which are given singly or repeated in series. Though it often gives these calls, the **Long-tailed Shrike** is similar to most other members of the family in that it only sings infrequently and unobtrusively. The song, though rarely heard, is unexpectedly elaborate. It lasts up to 15 minutes, and incorporates sweet warbles, whistles, and even some mimicry.

[*Lanius schach schach*, Xiamen, Fujian, China. Photo: Xue Juzheng]

The most vociferous shrikes are the two species of *Corvinella*. In common with most social birds, they call loudly, frequently, and with a wide repertoire of notes. Not only do they produce a variety of whistles, chatters, twitters and chirps, but they often vocalize in concert, either by duetting or chorusing. They also habitually call in flight. When an individual discovers an intruder on the territory, it produces a series of sonorous whistles, or in the case of the **Magpie Shrike**, a distinctive warbling noise. This seems to function as a rallying cry, as other group members soon arrive to strike up a complex chorus of whistles and scolding notes.

nest, the parental roosts tend to be in the nest tree. In Washington, the mean height of shrubs utilized by Loggerhead Shrikes for roosting was about 2.1 m, which was greater than the mean height for all the bushes in the surrounding area.

Shrikes search for prey from high vantage points, from which they swoop directly into hunting attacks. It is important, therefore, that they have perches of varying heights, as this allows the hunting of a wider size range of prey; as perch height increases, the average size of prey caught increases, perhaps because shrikes may not see the smaller prey items from high perches. Perch density in agricultural areas is inversely related to territory size and positively related to nutritional condition; a greater number of perches means that the chances of finding prey also are greater, the result being that a smaller territory is needed in order to sustain the bird, especially during the breeding season. Such perches can include both natural ones, such as shrubs, trees and stumps, and artificial ones, such as fence lines, utility lines and utility poles, and they are more exposed than are night-time roosts.

In coastal Texas, in the southern USA, perches are regarded as a necessary component of the foraging habitats of Loggerhead Shrikes, and the density of elevated perches has a direct influence on territory quality. In natural grasslands, those grasslands maintained through such processes as fire and low-intensity grazing, the shrikes utilized the abundant non-woody perch structures, such as sunflowers (*Helianthus*), partridge pea (*Chamaecrista*) and sesbania (*Sesbania*), more than they did other substrates. In agricultural and other non-natural systems, including crop fields, intensive grazing, hayfields, lawns and roadsides, they used primarily fence posts, utility lines and woody vegetation located in strips near the edge of fields. Shrikes may restrict their use of foraging substrate to that within 10 m of elevated perches, so that, in areas with a low density of perches, large areas of potentially good foraging are unexploited. This demonstrates the value of natural grasslands, which generally have non-woody perches evenly distributed throughout and which possess high vegetation diversity, thus allowing the shrikes to exploit a large proportion of the vegetation for foraging. In contrast, perches in agricultural habitats tend to be concentrated at edges. In Utah, shrikes were reported as hunting and storing food in large greasewood shrubs (*Sarcobatus vermiculatus*), and in Florida they used perches that were less than 5.5 m above the ground. In studies in South Carolina, Loggerhead Shrikes were reported as perching mostly on utility lines during the summer months, but using trees and shrubs more in the winter; it has been suggested, how-

ever, that this apparent difference is due to the fact that shrikes perched in trees were easier to see in the winter, when the branches are bare of foliage.

Mean estimates of the territory size of Loggerhead Shrikes in various parts of North America range from approximately 4.6 ha to more than 30 ha. Another criterion often used when determining area requirements is the distance between adjacent nests, some reports of which include 800 m in Nevada, 400 m in Colorado, 160 m in Alabama, 37 m in Indiana and 80–200 m in Alberta.

The black mask around the eye is a feature of many *Lanius* species, including the **Long-tailed Shrike**. It is thought to be a foraging adaptation, based on the fact that pale plumage would reflect and scatter more sunlight around the eye, perhaps reducing the acuity of vision. In theory, the black mask absorbs more light, making it easier to search for prey. Although difficult to test, this fits with the observation that foraging shrikes often perch facing the sun. Perhaps they are more likely to spot an insect if they can also see its shadow, or there may be less likelihood of the bird's shadow flushing the insect just before capture. Whatever the reason, shrikes regularly look into the glare of the sun when foraging.

[*Lanius schach*, Keoladeo Ghana National Park, Bharatpur, India. Photo: Jesús Rodríguez-Osorio]

Shrikes catch most of their prey on the ground by diving down from a high perch. Less regularly they also sally out to snatch winged invertebrates, or occasionally small birds, in mid-air. They are capable of hovering briefly to search for food but they mainly use elevated vantage points. The **Northern White-crowned Shrike**, for example, often scans for prey from bushtops, boulders and telephone wires. Like several other shrike species, it is sometimes observed perching on large mammals, in this case a domestic goat.

[*Eurocephalus ruppelli* ruppelli,
Lake Baringo, Kenya.

Both of these measures demonstrate a good degree of variation, with no apparent geographical trend, suggesting that range limits in themselves are not a predictor of territory size. Rather, territory size seems to be roughly correlated with fine-scale habitat quality, high-quality habitat resulting in smaller territories and, therefore, a greater density of nests.

Perches, in particular, seem to be an important determinant of territory size. As has been seen, the potential foraging area is likely to extend less than 10 m from a suitable perch, and territories that are sparsely vegetated are, therefore, usually larger. For example, Loggerhead Shrikes in dunes have territories 2–3 times larger than those of shrikes in moderately wooded sites, and the provision of additional perches in formerly unused foraging habitat resulted in a reduction in territory size and an increased density of nesting pairs. Moreover, it seems that shrikes may use the dispersion of trees as an indicator of habitat quality when selecting territories.

Southern Grey Shrikes have a distribution that includes the most extreme deserts. The thermoregulatory characteristics of these shrikes, determining how they manage heat balance in a wide range of thermal conditions, particularly those experienced in the hot Negev Desert of Israel, is of interest. The Negev shrikes were found to have physiological characteristics similar to those of most other passerine species of corresponding size, but with two notable exceptions. First, the rate of increase of evaporative water loss with increasing ambient temperature above the upper critical temperature was 40% higher than predicted for a bird of the same body mass and similar to that recorded for other desert-dwelling birds. Secondly, the shrikes' body temperature increased with increasing ambient temperature within the thermoneutral zone; this controlled hyperthermia leads to a saving of water. Resistance to heat loss was low compared with that of other small endotherms. During the summer, the standard operative temperature lies within the thermoneutral zone throughout the shrikes' morning and afternoon foraging periods; in the winter, it was below the lower critical temperature throughout the day. There was no significant relationship between the activity of these shrikes and the standard operative temperature in winter.

In ambient air temperatures of up to 40°C, the Loggerhead Shrike does not drink water. It has a basal metabolic rate that is lower than predicted for a passerine of its size, but is more similar to that of other raptorial species. In addition, it has an ex-

tended thermoneutral zone, ranging from approximately 24°C to more than 36°C. Indeed, K. G. Cunningham concluded that, as the species is a sit-and-wait predator, it may benefit from having a reduced basal metabolic rate. Its most metabolically expensive behaviour is flight, which it uses rarely. This shrike spends approximately 80% of its day perched, although it will spend more time in flight in areas of suboptimal foraging habitat.

Voice

The vocalizations of the family were well summarized by T. Harris and K. Franklin in their 2000 monograph. For many *Lanius* species, the song is relatively rarely uttered and is not far-carrying, although territorial calls are important. Shrikes use predominantly harsh calls, a feature from which the English vernacular name "shrike" is derived. The two *Corvinella* shrikes and some of the *Lanius* species combine harsh calls with whistles, the members of the latter genus having a warbling song, usually with mimicry. The Great Grey Shrike has been observed to lure vulnerable prey species by mimicking their calls.

The songs of most laniids consist of short trills and clear notes, varying in combination, tone and volume, the same song usually being repeated every few seconds. The vocalizations of males shift towards territorial defence once pair-bonds have been formed. The mate-attracting spring song incorporates higher, clear notes and fewer harsh screeches than the territorial song. Both males and females will give territorial warnings consisting of 4–10 harsh screeches.

Members of the genera *Eurocephalus* and *Corvinella* are gregarious, and often occur in groups. The basic song structure of the two *Eurocephalus* species is complex, their utterances being loud, with harsh squeaks, squawks and nasal bleating interspersed with stuttering, chattering and twittering calls, usually given in chorus. Duetting is well developed, and it, too, is often performed in chorus. These two species do not have any obvious territorial vocal advertisement, but the territorial call is started by the dominant individual in a group, which utters a bleating call, to which other group-members respond by chorusing with various stuttering, chattering and bleating calls combined with harsh sounds. Low growling noises are given in threat. The alarm calls of the white-crowned shrikes involve loud nasal calls given by

one individual, the others in the group immediately responding with repeated equally noisy calls. Little is known about the courtship calls of this genus, but the pair-bond is apparently maintained by means of duetting. The food-carrying adults emit bleating calls when approaching the nestlings, and the latter make persistent loud wheezy calls, although juveniles of the Northern White-crowned Shrike utter sharp, piercing "skeet" calls. At the roost, these species utter much calling before they finally settle, and purring growls and soft chortling sounds can be heard as individuals jostle for position and the flock-members huddle together on a branch.

Both of the *Corvinella* species are noisy birds, uttering a variety of loud sonorous whistles, harsh rasps, buzzing noises, and chattering, twittering and chirping sounds. They often duet, sometimes in chorus, and they often call in flight. They advertise the territory mainly by the use of visual signals, but these are accompanied by whistled calls. When a member of the group discovers one or more intruders infringing on the group's territory, it utters loud sonorous whistles or, in the case of the Magpie Shrike, a warbling call; these whistles and calls attract the rest of the group-members, which then join in with a complex chorus of various whistles and harsh calls. The intruding group uses similar calls, such as repeated whistles and harsh chattering, scolding, rattling, which develop into a loud communal chatter. In addition, the Yellow-billed Shrike utters a harsh grating and scolding alarm call, the corresponding vocalization of the Magpie Shrike being a short harsh phrase or a rasping note. The alarm calls usually bring the group-members together in order to repel the intruders.

The song of the Loggerhead Shrike includes a sharp, two-syllabled phrase, transliterated as "krrr-dí", "jée-uk" or similar, which is repeated at short intervals. Its calls are variable, and can contain elements similar to song phrases and interspersed with scolding notes, examples being "jaaaaa" and "teen raad raad raad". The calls of unpaired males are different from those of paired males, the mate-attracting song having higher, clearer notes and fewer harsh screeching elements. Most shrikes will ruffle the head and body feathers and emit buzzing or clicking calls when predators are detected. For the Loggerhead Shrike several predator warnings have been identified. The male gives a sharp two-note whistle with increasing cadence when the predator is at a good distance but approaching; this sharp whistle changes to a buzzing call, and the shrike creeps into cover or adopts a crouching posture, when the predator is almost overhead. In addition, a rapid clicking of the mandibles, producing a staccato clacking sound, is given when defending the nest-site, when a predator is close to fledglings, and during attacks on invading conspecifics. Alternatively, males use rasping buzzy "aak, aak, aak" calls, mostly against aerial predators. When mammalian and reptilian predators are close, they utter "jaa" calls accompanied by wing and tail movements.

Food and Feeding

Although there are seasonal variations, insects generally form the bulk of the diet of shrikes, and some species may be exclusively insectivorous. However, those species that breed in the higher latitudes rely exclusively on mammals and birds during the cold and snowy weather of the winter months. True shrikes will feed on relatively large prey, including small vertebrates such as reptiles, rodents and birds. Some invertebrates possess chemical defence mechanisms against predators, but the shrikes have evolved a method of overcoming this potential problem. They impale the prey on a thorn or similar sharp projection and consume it only after the chemical toxins have degraded, the cue to which appears to be the change in colour of the prey owing to detoxification and degradation over time. The removal of the sting of venomous invertebrate prey, such as wasps and bees and other Hymenoptera, appears to be innate and has been recorded for at least four species. The white-crowned shrikes in the genus *Eurocephalus* are known to eat millipedes (Diplopoda).

In the Northern Hemisphere, at least, the peak foraging times of laniids seem to be in the morning, but, as winter approaches,

daylight becomes shorter, and the temperature colder, an increasing amount of time in the afternoon is devoted to hunting, probably because prey activity at that time decreases. Typically, shrikes make 8–12 capture attempts per hour, but the number is highly variable. Capture success, too, varies widely, depending on habitat, prey availability, time of year, and the individual shrike's experience and skill; in a sample of various studies, it has been found that 28–85% of attempts result in a capture. Generally, shrikes increase their attack rate and capture rate during the breeding season.

During periods of great energetic demands, as at the height of the breeding season or at times of food shortage in winter, shrikes display their dietary flexibility. If necessary, they will even resort to frugivory. For example, Southern Grey Shrikes were observed to consume dates in Algeria, Lesser Grey Shrikes include cherries (*Prunus*) and figs (*Ficus*) in the diet, Woodchat Shrikes eat mulberries (*Morus*) in Crete, and Red-backed Shrikes consume rose hips (*Rosa*) in Scandinavia. A pair of Southern Grey Shrikes in an urban environment in Tunisia was observed to scavenge at hotel tables and to feed its young with food remains which included peanuts and bread. Shrikes have adapted to human encroachment in the landscape by hunting at birdfeeders.

Although shrikes generally capture prey that are smaller than the shrike itself, they are known also to capture and kill animals that are 3–5 times as large as their own body size or mass. One of the most striking examples involves the Southern Grey Shrike. In India, a saw-scaled viper (*Echis carinatus*) 25 cm long was found in a larder maintained by this shrike, and in Israel a fat sand rat (*Psammomys obesus*) and an intruding conspecific were impaled. In the USA, a Loggerhead Shrike in Florida was observed repeatedly to attack a large yellow chicken snake (*Elaphe quadrivittata*). Common Fiscals in South Africa sometimes catch and eat bats, and a wintering Great Grey Shrike in the UK captured a Northern House Martin (*Delichon urbicum*) in flight. Shrikes will also actively hunt in aquatic habitats by plunge-diving after their prey. A Common Fiscal in southern

For some shrikes, particularly those of open African savannas, the only suitable perches may be provided by megafauna. This **Common Fiscal** is making use of a handy white rhino (*Ceratotherium simum*). Large mammals such as this may increase the foraging efficiency of shrikes for more than one reason. Not only do they afford a good vantage point from which to search for prey, but they also disturb terrestrial invertebrates and attract large numbers of flying insects within range.

[*Lanius collaris*,
South Africa.

Shrikes are not terrestrial but they do capture terrestrial prey. The **Bay-backed Shrike** is typical in that it spends much time scanning 2–2.5 m above the ground on a high perch from which it dives down onto unsuspecting animals, usually within a radius of 10 m. It usually returns immediately to the same perch, or to a similar vantage point nearby, but it sometimes remains standing on the ground for several seconds. Most terrestrial prey species are insects, including many beetles (Coleoptera) and grasshoppers (Orthoptera).

[*Lanius vittatus vittatus*, Jaipur, Rajasthan, India. Photo: Gaurav Bhatnagar]

Africa was seen to hunt tadpoles of the African clawed frog (*Xenopus laevis*), and Loggerhead Shrikes in Florida hunted blue crayfish (*Procambarus alleni*). In India a Southern Grey Shrike specialized in slugs (Gastropoda), and in Germany a Great Grey Shrike was observed to catch, impale and consume white-lipped snails (*Cepaea hortensis*) and Roman snails (*Helix pomatia*) during the winter. Shrikes are also opportunistic, and they will feed on carrion and scavenge at prey remains left by raptors or at roadkills. During the breeding season they may cannibalize their own dead nestlings, irrespective of the cause of death.

Slovak and Polish researchers were able to demonstrate a link between a species' phenotypic characters and its diet. In a study of the Great Grey Shrike, they found that the composition of the diet was non-random; smaller individual shrikes foraged mainly on beetles, while individuals with longer wings and tail preyed on flying and plant-dwelling insects.

Laniids choose foraging habitats that are especially abundant in large insects and small reptiles and rodents. Studies of the Red-backed Shrike's diet in relation to prey abundance in Spain revealed a negative selection for Orthoptera, whereas beetles (Coleoptera) and Hymenoptera were positively selected. This is in contrast to south-west Finland, where the shrike was found to prey on Orthoptera and carabid beetles in an abundance-related manner.

A seven-year study of the diet of the last two French breeding colonies of Lesser Grey Shrikes showed that, in accordance with information from other breeding colonies across the species' distribution, the main prey during the nestling and fledgling stages were beetles, grasshoppers and locusts (Acrididae). It was discovered that the diet of pairs in loose colonies was different from that of pairs breeding solitarily. At colonies, the beetles *Amphimallon pygialis* and *Anisoplia tempestiva* and the white-faced bush-cricket (*Decticus albifrons*) accounted for 60% of the diet, whereas these species represented only 10% of the food of solitary pairs. This may be attributed mainly to the fact that colonies were located within hunting distances of meadows, and solitary nests were not. The latter were mostly in vineyards, cereal fields and vegetable plots.

Studies of the diet composition of Great Grey Shrikes in the period October–March during nine winters in southern Finland showed that the main prey was *Microtus* voles, which formed 35.4% of vertebrates taken, followed by the harvest mouse

(*Micromys minutus*), at 27.5%, the common shrew (*Sorex araneus*), at 14.8%, and the house mouse (*Mus musculus*) and a variety of birds, each of which accounted for 7% of vertebrates consumed by this laniid. Invertebrates constituted only about 0.1–1.7% of the total prey biomass. The shrikes hunted birds in an opportunistic manner; no preference for larger species within the suitable size range was evident, but tits (Paridae) dominated, accounting for 61.2% of all birds eaten. This was not due to a greater availability or to prey selection but, rather, was a result of the greater vulnerability of tits. The hunting of voles decreased in mid-winter and during periods with snow, whereas the proportion of birds and, especially, mice in the diet showed a corresponding increase at these times.

The shortness of the winter daylight period in Finland limits the possibilities for hunting. Calculations estimated the mean daily amount of captured prey as 36.3–59.8 g, and the mean daily food consumption as 44.1–62.6 g, both parameters being lowest in mid-winter. Increased capture efficiency, rather than increased hunting effort, enabled the shrikes to catch a fairly constant number of prey items each day, irrespective of time available for hunting. With a decrease in the amount of daylight, the shrikes showed signs of increased hunting activity in the morning and evening twilight. They responded to shortened daylight time by reducing the interval between meals, so that the percentage of the daylight time used for feeding increased as the photoperiod shortened. In this way, the shrikes adjusted their foraging and feeding behaviour in order to achieve a stable prey-capture rate and food consumption without increasing the energy costs.

Farther south, a study of the breeding-season and winter diets of the Southern Grey Shrike in south-west Europe revealed that this species fed mostly on cold-blooded prey such as beetles. Vertebrates were seldom taken except during the fledging period, when the adults caught small passerine birds. Marked seasonal differences were found. Hymenoptera were consumed largely in the autumn, arachnids in the autumn and winter, Orthoptera in summer and autumn, and Lepidoptera larvae in winter and spring and by fledglings. Nevertheless, beetles were ingested in large proportions throughout the year; carabids were the main prey in winter and beetles of the family Melolonthidae were especially important for adults during the nestling period, as were cetoniid species for the fledglings. Small mammals and small birds were exploited less by the nominate race in France

and Spain than by the subspecies *theresae* and *elegans* in Israel, whereas the opposite might be expected from a north-south climatic gradient.

Geographical variation in feeding has been reported both between species and among subspecies. Important differences can be observed in the main prey consumed by the Great Grey Shrike and the closely related Southern Grey Shrike according to latitude. One is the presence in the diet of mammals, which are the most important prey of the Great Grey Shrike in northern geographical zones and the frequency of which decreases with latitude. In the Canary Islands, one of the most southerly latitudes examined, mammals were not frequently captured by the local race *koenigi* of the Southern Grey Shrike, probably because the two small mammals available for the shrike on Tenerife are essentially nocturnal. It was found that the highest rate of predation on mammals occurred in spring. In mainland Spain and France, on the other hand, the nominate race of the Southern Grey Shrike preys on mammals most frequently in autumn and winter. The presence of reptiles in the diet, however, increases towards the southernmost latitudes. The importance of reptiles in the shrike's diet in the Canaries could be influenced by the high availability of lizards, one of the main ecological characteristics of these islands.

Throughout its range, the Loggerhead Shrike's principal food during warmer months seems to be arthropods, especially grasshoppers where these are abundant, but small vertebrates, such as amphibians, reptiles and small mammals, are regularly taken, as are other passerines. Vertebrates are of greatest importance in the colder months, when arthropod abundance declines, and they can sometimes account for 50–76% of the shrike's diet. Reptiles and amphibians, often combined under the term "herptiles", are taken mostly in the spring, when the herptile populations are high, following hatching events, and the juvenile shrikes are learning to forage. Birds are taken usually in the winter and spring, which are energetically intense periods for wildlife. These birds are usually of the same size as or smaller than the shrike itself, but larger prey recorded as being taken include, for example, the American Robin (*Turdus migratorius*) and the American Mourning Dove (*Zenaidura macroura*). Mammals, too, are captured primarily in winter, although with less frequency than birds, probably because they are less accessible beneath a snow layer during

temperate winters. In various studies, the dietary components of Loggerhead shrikes were, by number of prey items, 68% insects, 4% spiders (Araneae) and 28% vertebrates, although the latter, because of their larger size, may comprise a greater portion of the biomass consumed.

A list of specific prey items of the Loggerhead Shrike reported in the general literature incorporates a wide range of species. Mammals listed include the meadow vole (*Microtus pennsylvanicus*), sagebrush vole (*Lemmys curtatus*), white-footed mouse (*Peromyscus leucopus*), pocket mice (*Chaetodipus*), kangaroo rats (*Dipodomys*), shrews (Soricidae) and the thirteen-lined ground squirrel (*Spermophilus tridecemlineatus*), with one record of a full-grown cotton rat (*Sigmodon*); birds include the Chimney Swift (*Chaetura pelagica*), New World warblers (Parulidae), sparrows and buntings (Emberizidae), finches (Fringillidae), a single record of a Northern Cardinal (*Cardinalis cardinalis*), American Mourning Dove and Horned Lark (*Eremophila alpestris*); in addition, the American green tree-frog (*Hyla cinerea*) and its relative the spring peeper (*Pseudacris crucifer*) are recorded as prey, and invertebrates listed include grasshoppers, crickets (Gryllidae), beetles, butterflies, moths, bees and spiders. On one South Carolina island, analysis of Loggerhead Shrike pellets indicated that earwigs (Dermaptera) formed 17.1% of the species' diet, ants (Formicidae) 13.9%, crickets 13.1%, grasshoppers 8.7%, and side-blotched lizards (*Uta*) 6.7%. In New Mexico, a shrike was seen to be carrying, presumably having killed, a desert massasauga rattlesnake (*Sistrurus catenatus*) about 40 cm long and weighing some 35 g, although this is probably an abnormal case.

In general, it seems that shrikes select smaller, easier-to-catch prey when these are available, and that they attack larger prey opportunistically and in times of food scarcity. Shrikes occasionally take carrion and scavenge meat scraps left by raptors, which may represent a "last-resort" food source during the winter months when live prey are scarce. Some individual variability in prey choice is apparent, some individuals having a preference for specific types of prey.

Pellets, which are regularly regurgitated by all laniids, collect at the base of the favourite perches or impaling sites within a shrike's territory. They contain the indigestible parts of the prey, and include bones and fur of mammals, bones and feathers of

True shrikes are capable of capturing surprisingly large prey, including some rodents. However, the tendency to hunt vertebrates varies widely. Tropical species are often largely insectivorous, but those of higher latitudes may rely exclusively on birds and mammals during cold weather. In the snowy Finnish winter, for example, the **Great Grey Shrike** survives by consuming large numbers of *Microtus* voles, harvest mice (*Micromys minutus*), and common shrews (*Sorex araneus*). Unlike raptors, all shrikes capture and kill vertebrate prey with the beak, rather than with the feet. When conditions are particularly tough, they are also known to scavenge carrion or meat scraps left at raptor kills.

[*Lanius excubitor excubitor*,
Liminka, Finland.

birds, bones and skin of reptiles, and the chitinous remains of invertebrates. Pellets are formed 40–50 minutes after the shrike has consumed a full meal. Study of these pellets is a widely employed technique for identifying the diet of shrikes; the results, however, must be treated with caution, because they tend to underestimate those prey having soft body parts and, of course, those that are completely digested.

A study of Red-backed Shrike predation on small mammals at León, in north-west Spain, was based on pellet analysis and the identification of prey caught, and compared the chosen diet with prey availability. The shrikes preferred mammals associated with forest edge and open areas with scrub, avoiding those of wooded areas. They caught both young and adults of smaller species, but only young of larger ones. The local habitat use and diet of Red-backed Shrikes were studied also in south-west Finland. From an analysis of a total of 688 pellets, carabid beetles constituted 29.1% of the prey and bees, especially bumblebees (*Bombus*), 18.3%; the rest was made up mainly of representatives of other beetle families, with 21.6%, other Hymenoptera, with 12.6%, and Orthoptera, 8.3%. In the diet, beetles decreased whereas Apidae and Orthoptera increased as the season progressed, reflecting changes in the abundance and the vegetation-dependent availability of these insects. Breeding shrikes were found in natural unmowed meadows and in areas created by forestry, and there was little difference between the two habitats in terms of the shrike's territory size, the starting date of incubation, breeding success, and the abundance of the main prey and its percentage of the diet. In the post-breeding season, however, shrikes showed a particular preference for meadows, this in part related to a high abundance of Orthoptera in this habitat, which was corroborated by diet analyses. In addition, factors minimizing the risk of predation, such as the open aspect of meadows, may have contributed to the observed habitat selection.

In another study of the dietary preferences of the Red-backed Shrike, this time in Poland, and based on analysis of prey remains in pellets, at impaling sites and in nests, the diet consisted almost totally of insects. The proportions of the different taxa, especially for hymenopterans and orthopterans, varied according to the method of food analysis. There were significant differences in species composition when this was evaluated separately

for each of the sites within a shrike's territory. Red-backed Shrikes evidently preferred beetles and hymenopterans, and avoided flies (Diptera) and arachnids, the degree of preference again depending on the method of analysis used.

A comparison was made between a nesting Great Grey Shrike, representing a small predator, and a nesting Common Kestrel (*Falco tinnunculus*), a larger predator, hunting in the same clearing. Both predators carried most large prey, in the form of mammals, to the nest and consumed all small prey, insects, at the capture site. The smaller predator, the shrike, carried most lizards, representing medium-sized prey, to the nest, whereas the larger kestrel consumed most lizards at the capture site, although the distance from the capture sites to the nest was the same for each predator. If this pattern applies in general, it is likely that traditional nest-based food analyses overestimate the proportion of lizards in the diet of the Great Grey Shrike and underestimate it in that of the Common Kestrel.

The ability of predators to kill prey depends on the ease with which the latter can be captured and handled, and the matter of prey vulnerability therefore becomes one of paramount importance. There is a direct relationship between the difficulty of capture of a prey species and the proportion of substandard individuals of that species in a shrike's diet. This was found to be the case especially when shrikes fed on birds, as opposed to when they fed on rodents. In ordinary conditions, shrikes tend to ignore healthy individuals because of the energetically expensive challenge of capture, but predatory behaviour appears to be stimulated by circumstances that render such prey vulnerable to attack. For example, the Loggerhead Shrike has been observed to grab a Savannah Sparrow (*Passerculus sandwichensis*) seconds after it was shot and hit the ground, and to catch and impale a Grasshopper Sparrow (*Ammodramus savannarum*) after it was hit by a truck; this laniid has been seen to seize birds when they were feigning injury, or attending nests, or in exposed situations in open areas.

The effects of Southern Grey Shrikes on the seed dispersal of the solanaceous plant *Lycium intricatum* were studied on Alegranza, a small xerophytic island in the Canaries. Totals of 146 shrike pellets and 123 Atlantic lizard (*Gallotia atlantica*) droppings were analysed, and the pellets were found to contain 611 *Lycium* seeds and the lizard droppings 224. *Lycium* fruit remains, including seeds, were present in 50% of the pellets and 31.7% of the droppings. Intriguingly, there was a significant coincidence of *Lycium* seeds with the presence of lizard remains in shrike pellets, and it seems clear that seeds in the shrike pellets originate from fruit consumed by lizards that have subsequently been preyed on the shrikes, and not directly from fruit eaten by the shrikes themselves. Seeds from shrike pellets had significantly higher germination rates than did those from uneaten fruits and from lizard droppings, and it seems probable that differences in retention time and treatment in the gut between the two species are main factors influencing the germination process. It has been estimated that a seed takes on average 2.42 days to pass through the gut of the Atlantic lizard, whereas a seed is retained inside a shrike gizzard for a much shorter time, only 45–55 minutes. This appears to be an example of the very poorly known phenomenon of indirect seed dispersal, which seems to play a comparatively important role on small islands where the interaction between animals and plants is very intense.

Still in the Canary Islands, the diet and prey selection of the Southern Grey Shrike were studied in the xeric coastal area of Tenerife. The main aim of this study was to compare the diet on Tenerife with those of continental populations of the Southern Grey Shrike and those of the Great Grey Shrike. A total of 5112 prey items from 440 pellets was analysed, and the majority of the prey, 85.4%, was found to consist of beetles, mainly of the families Curculionidae and Tenebrionidae, the rest consisting of other arthropods and vertebrates. In terms of biomass, the bulk was made up mainly of vertebrates, especially lizards, which accounted for 64%. Although slight seasonal variations were apparent, beetles and lizards featured prominently in the diet in all seasons. A positive selection for some beetles and some non-formicid Hymenoptera, and also for the desert locust (*Schistocerca gregaria*), was detected. The importance of lizards in the diet of

Intensive studies of the Loggerhead Shrike have revealed that roughly 70% of its diet consists of insects. In addition, it consumes a range of other arthropods, such as spiders (Araneae) and crayfish (Decapoda). The rest of the diet is made up of vertebrates, including frogs, rodents, birds and reptiles. Amongst some of the unexpected prey items are the thirteen-lined ground squirrel (Spermophilus tridecemlineatus), the Chimney Swift (Chaetura pelagica) and the American green tree-frog (Hyla cinerea). This bird has captured a horned lizard (Phrynosoma).

[*Lanius ludovicianus*, Texas Forshage Ranch, Edinburg, Texas, USA. Photo: Bill Gozansky/VIREO]

this insular shrike population could be related to three ecological factors: the high abundance of lizards on such islands, the greater effectiveness of predation, and the lower energy investment required to capture them. The data accord with the hypothesis that the Southern Grey Shrike relies on cold-blooded prey in hot weather, such as the south of France, whereas the Great Grey Shrike relies mainly on warm-blooded prey in cold conditions, as found in Scandinavia.

Selective predation by Southern Grey Shrikes on small mammals was studied in north-western Spain. The shrikes favoured semi-open habitats and, as a consequence, exhibited a preference for the species of small mammal associated with forest edge, farmland, scrubland and other open areas with scattered shrubs and trees. They avoided small-mammal species related to other habitats. The shrikes did not discriminate among the sizes and ages of small species of shrew, mouse and vole, but they did prefer smaller and younger individuals of medium-sized species.

Shrikes are "sit-and-wait" predators, spending a great deal of time on perches of various kinds. They catch their prey mainly on the ground, but in fair weather, when aerial insects are often numerous, they catch many winged invertebrates by hawking them in the air. They also hover at times. Co-operative hunting by shrikes appears to be rare, and there is only one published report to date: in eastern Oregon, USA, a pair of Loggerhead Shrikes were seen combining to kill a garter snake (*Thamnophis*) and carrying it to their nest.

The hunting behaviour of Woodchat Shrikes in northern Switzerland was studied by direct observation of five pairs. The shrikes fed only on arthropods, preferring larger ones, although in poor weather they were dependent on smaller ones. During warm and dry weather the insect activity increased, and more insects were seen in tall vegetation than in short growth. The shrikes hunted both on the ground, which accounted for 64% of attacks, and in the air, where 36% of capture attempts were made. Ground-hunting was practised mainly in areas with short vegetation, on average 7 cm high, and in terms of energetics was of greater benefit than was aerial flycatching owing to the larger average prey size and the shorter hunting distance involved. The proportion of time which the adults spent in flight was longest during the nestling stage of breeding. The total hunting activity of the adult shrikes was slightly increased during the incubation and nestling stages, but reduced in

the period before incubation and after the fledging of the young. It appeared that the Woodchat Shrikes in this study spent less time in flight when hunting over short vegetation than when hunting over taller growth.

Soobramoney and colleagues analysed the variations in foraging behaviour of four subpopulations of colour-ringed Common Fiscals along an altitudinal gradient in South Africa, revealing some interesting results. There were clear differences between the four subpopulations in the height of perches used, the attack distance and the length of prey, as well as in the rates of attack, capture and success. During winter, the fiscals obtained more food by increasing their attack and capture rates and by taking larger prey items. Foraging success varied according to the size of prey attacked, and, with the exception of one subpopulation, was higher in winter than in summer. Common Fiscals exhibited considerable variability in feeding strategies and foraging parameters, and showed that they are highly opportunistic. Invertebrate prey was important, accounting for more than 90% of items, while vertebrates made up less than 10%. The authors of this study reasoned that, even if shrikes seek to maximize their chances of locating larger, higher-energy prey, the low capture rates of these, combined with the short duration of hunting attempts when capturing smaller prey, mean that small prey can be taken with little cost while waiting for "better" food items to appear.

Mackinnon's Shrike (*Lanius mackinnoni*) in Central Africa has been observed to follow carnivorous ant swarms when on forest edges, and to prey on insects attempting to escape from the ants. In western Poland, the Great Grey Shrike preyed on adult amphibians, including poisonous toads. These shrikes practised a novel form of behaviour, skinning the toads before consuming them. This action is logical, because, like the parotid glands behind the toad's eyes, toad skin is poisonous, containing irritant bufotoxins. Although amphibians were present in a large number of the shrike territories being studied, in only a few of these did the researchers record cases of predation on amphibians, including toxic species. Only a few adult shrikes from the population studied were able to feed on toxic amphibians, indicating that individual experience may perhaps play a crucial role.

Although having stronger legs than those of other passerines, and despite being similar to diurnal raptors in their predatory behaviour, the Laniidae do not possess the strong talons of the raptors, utilized by the latter when dismembering prey. It has been

Many species of *Lanius* appear to subsist on a diet made up largely of orthopterans. This is presumably a function of the abundance of grasshoppers and their relatives in the grassy or shrubby habitats favoured by shrikes. The other main quarry are beetles (Coleoptera). In migratory species, such as the **Isabelline Shrike**, there is much seasonal variation in diet. In terms of species composition, there is little overlap in insect fauna between the Asiatic breeding grounds, the East African wintering grounds, and migration stopovers in the deserts of the Middle East.

[*Lanius isabellinus*, Sun Farms, Sohar, Oman. Photo: Hanne & Jens Eriksen]

suggested that they have overcome this limitation by evolving the behaviour of impaling prey or wedging food items in branch forks, which permits them to increase the size of exploitable food items. The unpredictable and transitory nature of food surplus seems to have been a crucial factor in the initiating of impaling behaviour. Moreover, the composition of caches of impaled food was found in several studies to be a function of the distribution and accessibility of the prey. Nevertheless, shrikes are able to grasp prey with the foot, and to eat smaller items or dismembered pieces of larger prey in the manner of a parrot (Psittacidae), by raising the foot to the bill.

In the context of the Laniidae, "impaling" is defined as the skewering of prey on a sharp projection, such as a thorn, twig or barbed wire. "Wedging" is the placing of the item in the fork of a branch, barbed wire or similar substrate, allowing the shrike to manipulate and feed on the food. Almost all *Lanius* shrikes impale their prey, but the regularity of this behaviour varies among species and even within species. It is a regular practice of the larger shrikes, which need to "anchor" vertebrate victims in order to dismember and eat them. The evolutionary development of this unique behaviour, however, is unstudied, although its ontogeny in young shrikes is well known. Other avian groups display similar types of behaviour. For example, some Australian butcherbirds (Cracticidae) and African Southern Boubou Shrikes (*Laniarius ferrugineus*) are known to wedge prey in forks, apparently to save handling time, but these species never impale prey on thorns. In contrast, the Laniidae impale vertebrate prey on sharp objects, decapitate them and, in most cases, consume the brain before other body parts. Both wedging and impaling are considered to facilitate the dismembering of prey items at lower energetic cost to the predator.

Most studies of impaling have focused on one or more of four species, namely the Loggerhead, Red-backed, Woodchat and Great Grey Shrikes. Field observations confirm that the ability to impale prey develops in the young of these species in the first four to five weeks after fledging; although impaling may be innate in young shrikes, it has been found that it could be mastered only through practice and experience. This idea is consistent with the findings that, among avian predators, capture rate, capture efficiency, prey size and handling time improved with the age of the individual, indicating that there is a learning component in avian predatory behaviour. The type of implements available during a young shrike's learning period will determine its impaling tendencies for the rest of its life; shrikes raised in the vicinity of thorns favour impaling on thorns, while those which are accustomed to the presence of branch forks and the like in their surroundings prefer to wedge their prey.

After capturing a prey animal, the shrike transports this to a perch. Smaller prey items, those equivalent to 9–58% of the shrike's own body weight, are carried in the bill, while larger prey, those 61–131% of its body weight, are carried in the feet. Once at the perch, the shrike snaps the neck of its victim, using the tomial notch of its bill or a sharp blow to the back of the prey's head.

During the breeding season, many impaled prey items are stored to form a cache, or "larder", which serves to attract mates and to allow females to feed during incubation without leaving the nest vicinity. In a study of the temporal and spatial patterns of impaling exhibited by a migratory population of Loggerhead Shrikes, it was found that in 88% of 24 breeding territories the pair impaled prey. Insects and reptiles were the most common victims, comprising 56% of such animals. The number of impaled prey was highest during the nestling stage, and shrikes also impaled items at sites closer to the nest during this stage than during either the incubation or the fledging stages. There was a positive correlation between the abundance of impaled prey and the number of young fledged from the nests. The results suggested that potential or realized demand was a major factor affecting impaling patterns, and that supplemental food for delivery to incubating females and to nestlings was a significant function of impaling during the breeding season.

A similar study was undertaken in western Poland, this time involving a resident population of Great Grey Shrikes. Several seasonal shifts in the pattern of impaling behaviour were apparent, these being expressed as changes in the prey species found at larders, the level of food consumption and the concealment of impaling sites, as well as in the spatial distribution of larders. During the pre-breeding period, males impaled more prey before mating than they did afterwards, the majority of larders were located on borders of territories and in exposed sites, and a large proportion of the impaled food was left uneaten. All of this suggests that during the mating period impaling behaviour has a signalling function. During the breeding stages, on the other hand, the distance from larders to nests decreased, more prey were stored in well-concealed sites, and a larger proportion of the stored food was consumed; in this period, therefore, impaling was primarily a means of storing food.

Another study focused on the temporal and spatial patterns of food-caching by two sympatric species in north-west Spain, the Southern Grey Shrike and the Red-backed Shrike. It was found that Southern Grey Shrikes stored food mainly during the non-breeding season and Red-backed Shrikes during the breeding period, the incidence of caching being dependent on prey availability and the shrikes' energy requirements. For example, the food-caching rate of Red-backed Shrikes increased as the number of nestlings increased. Southern Grey Shrikes used 62% of their stored prey, most of it within nine days. Red-backed Shrikes, however, usually utilized their caches within 24 hours, mainly at dawn and dusk, and used 88% of their stores. The preferred sites for larders were hawthorn and blackthorn (*Prunus*) bushes with long, thin and cylindrical thorns, whereas rose and bramble (*Rubus fruticosus*), which have short, broad, laterally flattened thorns, were avoided by both species. Red-backed Shrikes scattered their larders; the distance between the nest and the stored food depended on the availability within the shrike's territory of suitable thorny shrubs, but there was a tendency to impale food close to the nest.

In this Spanish study, the shrikes selected the upper and inner parts of the shrubs for caching, presumably in an attempt to conceal the food from potential kleptoparasites. In addition, there was an apparent link between prey colour and the colour of the bush on which it was stored, suggesting that cryptic coloration was a factor in the choice of cache site. Nevertheless, at least 6% of the prey stored by the Red-backed Shrikes was lost, mainly to wasps. It is of interest that kleptoparasitism has been recorded in several other studies. Prey animals impaled in conspicuous sites are especially susceptible to being stolen by neighbouring shrikes, or by transient or dispersing individuals moving through the area. Moreover, predators such as Little Owls (*Athene noctua*) and kestrels from neighbouring territories sometimes steal the shrike's caches in order to supplement their own diet, some even doing so on a regular basis.

Millipedes (Diplopoda) are rather noxious creatures, and they appear to be avoided by most birds.

The only shrikes reported to eat them are the African species in the genus Eurocephalus, although the related Yellow-billed Shrike can be added to the list, as this photograph attests. This individual may have unearthed its prey while feeding on the ground, as the species has occasionally been observed hopping about, turning over leaf litter and pulling worms from soft earth in a very unshrike-like manner.

Shrikes habitually manipulate their prey to prepare it for consumption. In the case of venomous invertebrates, such as wasps, bees and other Hymenoptera, this involves removing the sting from the abdomen. The technique of sting-removal appears to be innate, and has been reported from several members of the family. Even non-venomous insects tend to be beaten against a hard surface, or shaken rapidly with the bill, as demonstrated by this juvenile **Common Fiscal**. These manipulation techniques help to remove wings, legs, carapaces and other indigestible body parts.

Caches made prior to pair-bonding and before the onset of the breeding season may indicate to females the quality of individual males, and the latter's potential to supply sufficient food for the female and young. During the prenuptial period, male shrikes have been observed to impale inedible objects such as rags, snailshells and eggshells, faecal sacs and even bread crusts, ostensibly to boost the visual impact of the cache. It has been suggested that male quality might be assessed not only by the visual impression of the cache, but also by the species composition of the larder, even though such caches are subject to kleptoparasitism. In addition, fitness has been found to be positively correlated to initial cache size. Males with larger caches not only had greater breeding success but also were more frequently polygynous. The fact that shrikes often persist in maintaining conspicuous larders even when their young have hatched and that they impale inedible objects while under constant threat from kleptoparasites, which may even endanger their young, has prompted several authors to suggest that such "exhibitionism" might assist in reducing the energetic costs of territorial defence during the most strenuous part of the birds' annual cycle. In fact, it is thought that impaling may play a role in the advertising of territory ownership and in defining territorial boundaries. Other suggestions are that food-hoarding, the creation of a larder for later use, is the major function of impaling. It was also proposed that the impaling by shrikes of old nest material for subsequent reuse could result in inedible objects remaining impaled after the new nest has been constructed. K. M. Burton suggested that this behaviour could have been the progenitor of the impaling of large prey items for dismemberment. Others have theorized that impaling might serve to divide tasks between the parents, such that the males hunt and impale prey while the females feed themselves and their young from the larders.

Impaling appears to be an innate behavioural characteristic that is refined by learning and practice. Fledgling shrikes play with inedible objects while still being fed by their parents, and they indulge in "dragging" behaviour that later develops into what has been termed "dabbing", which involves holding the prey with the tip of the bill and thrusting it towards nearby objects. Once the young are able to catch their own prey, they develop individual variations in their prey-handling techniques. Young shrikes use the act of impaling solely as a means of facilitating the dis-

membering of prey. They also return to use sites where they had successfully impaled items previously, usually at places where they had engaged in dabbing, and it appears that this fidelity to impaling sites has carried over into their adult life.

An interesting utilization of impaling for a purpose other than that for which it evolved, a phenomenon known as exaptation, was found for Loggerhead Shrikes in the USA. Aposematically coloured lubber grasshoppers (*Romalea guttata*), which possess chemical defences, were impaled by these shrikes, left until the deterrent chemicals had decomposed, and only later consumed. Sexual selection by females appears to have been a force behind the various other exaptations of impaling reported to date. One may hypothesize that in the past, when females arrived at the breeding grounds, they evaluated the male and his territory quality by observing the locations of his cache sites and their contents; in response to the females' behaviour, the males probably resorted not only to killing more prey than they needed and impaling the surplus in their caches, but also to adding small prey items that could otherwise be consumed with relatively little handling cost. In order to enhance the visual impression of the cache, males also impaled objects that were inedible but often colourful, and it was probably at this stage that aposematically coloured, chemically defended insects were impaled, initially as visual cues but later, after detoxification, becoming edible. The culmination of this process is that those males having the biggest food larders mate with the earliest-arriving females, enabling them to make more than the average number of nesting attempts and to produce a large number of young, or, in extreme cases, to breed simultaneously with two females.

During the courtship-feeding stage (see Breeding), the food offered to the female by the male is invariably fresh. Later, when the female is incubating or brooding the nestlings, the male can supplement the prey brought to the nest with items from his larder, replenishing the cache when time allows. Male Southern Grey Shrikes do not feed the chicks until the latter are at least five days old, the nest being the exclusive domain of the female, which does all the brood-feeding. Incubating or brooding females have been observed to fly to and eat directly from the cache. The amount of prey in these larders drops significantly during the fledging and post-fledging periods, when the young consume all the food and the parents impale only in order to dismember the larger prey

items, the pieces being then transported to the young. In most cases when an impaled vertebrate was decapitated, the male consumed the brain and the head, and the body was delivered to the female and the young.

A study of the Lesser Grey Shrike in Slovakia revealed that in natural conditions this species seldom stored food or impaled prey. Only when the shrikes were experimentally provided with a temporary, spatially clumped food surplus did they hoard food, and repeated exposure to such surpluses significantly increased the impaling rate. It was suggested that the low caching rates of the shrikes might be due partially to lack of experience. Males, rather than store food, preferred to feed any surplus to the female. The researchers concluded that the Lesser Grey Shrike is likely to cache prey only when its immediate food needs are satisfied as a result of a temporary abundance of suitable prey, a situation which probably occurs seldom in nature. This variable, combined with a probable dearth of suitable impaling sites, may result in there being few stimuli for shrikes to cache food, thereby limiting the learning process in this species. This, in turn, could explain why the Lesser Grey Shrike has a comparatively poorly developed propensity for impaling and hoarding food.

So far as is known, neither the two *Corvinella* species nor the two *Eurocephalus* white-crowned shrikes impale their prey. Unlike the *Lanius* shrikes, the members of these two Afrotropical genera appear not to store food.

Breeding

Monogamy is the predominant breeding system of most of the Laniidae. Nevertheless, under certain environmental pressures, such as biased sex ratios wherein females outnumber males, or when a marked difference in quality among males is observed during the pre-breeding season by females (see Morphological Aspects), several species may sometimes practise polygyny. Po-

lygyny has been recorded for Southern Grey Shrikes in Israel, for Great Grey Shrikes in Austria and Poland, for Red-backed Shrikes in Poland and Sweden, and for Loggerhead Shrikes in North America. Polygynous pairs of Southern Grey Shrikes in Israel had the choice of two different breeding strategies. Males with large food caches used a different strategy from that adopted by conspecifics with small caches. Pairs with large caches used a parallel strategy: the females laid a second clutch soon after the first had hatched, and males cared for the first brood. Those pairs with small caches employed a serial strategy: both parents cared for the young until the latter fledged, the male doing all of the provisioning, and the females laid the next clutch after the first brood had fledged. Pairs which adopted the parallel strategy were significantly more productive, having more breeding attempts, laying many more eggs and rearing many more young in the season than pairs which adopted the serial strategy.

Extra-pair copulations have been recorded for at least five members of the Laniidae. They can be costly for both sexes, especially if they are detected by a social partner. The threat of extra-pair fertilization of the partner could result in reduced parental investment or divorce. In order to reduce the costs of extra-pair copulations, natural selection may favour behaviour that reduces the likelihood of its being detected by a partner. Moreover, habitat structure may influence the efficiency of a male's mate-guarding behaviour and, therefore, the possibilities of occurrence of extra-pair copulations. In studies of the Great Grey Shrike, a socially monogamous passerine of semi-open habitats, it was found that individuals of both sexes selected more secluded sites for extra-pair copulations than for within-pair copulations. For females, the costs of participating in extra-pair copulations are an interesting topic. An obvious potential cost to females, one proposed in theory, is that of physical sanctions by the male partner, although retaliation and punishment by male partners have not been experimentally demonstrated. A team of European researchers, combining field observations and a field experiment, found that, with the Lesser Grey Shrike, there was a high rate of intrusion by extra males during the female's fertile period, and that extra-pair copulations occurred in the population; when females were "detained" during the fertile phase, males retaliated physically against their partners, thereby increasing the costs related to female extra-pair behaviour, but there were no obvious costs to males of "punishing" the mate. Interestingly, DNA-"fingerprinting" revealed that, in this Lesser Grey Shrike population, extra-pair paternity was rare or non-existent, although it could not be proven that this apparent monogamy at the genetic level was the result of male retaliation. The researchers suggested, however, that in future studies the males' strategies should be considered when attempting to explain interspecific variation in extra-pair paternity.

Further, the aggressiveness of male shrikes during the fertile period of their females may be a method of preventing extra-pair copulations. Hence, the level of aggression of Red-backed Shrikes was tested experimentally, by placing a stuffed male at a distance of, in most cases, 10–20 m from active nests. At each stage of the breeding process some males ignored the dummy or did not more than approach it, while others attacked it weakly or fiercely. With two exceptions, the breeding females took no notice of the stuffed male. The reactions during the nest-building and laying periods were, on average, stronger than those during incubation, diminishing further during the nestling stage.

In the USA, a genetic study of Loggerhead Shrikes in Oklahoma used six nuclear microsatellites in order to assess the extent of intraspecific brood parasitism and extra-pair paternity among 218 offspring from 44 broods. In this, the first genetic assessment of parentage in a wild population of Loggerhead Shrikes, it was apparent that no offspring were the result of intraspecific brood parasitism, but eight young from five families, representing 4% of all offspring, had been sired by extra-pair fertilization.

Overlap among the home ranges of breeding male Red-backed Shrikes in a valley in the Lombardy Alps, in Italy, was correlated with the results of DNA-fingerprinting for six family groups. One out of 19 young had paternity different from that assumed on the basis of behavioural observations. In addition, after the young

Once insects have been captured, and duly beaten and prepared for consumption, shrikes often eat their prey directly. As with most insectivores, they will often manoeuvre large prey in the bill to ensure that it is correctly orientated. This **Chinese Grey Shrike** has returned to its hunting perch to swallow a recently caught orthopteran in typical fashion: head first. This large species, a member of the *Lanius* excubitor group, occurs widely in East Asia from Mongolia and Russia across much of China to Korea.

Photo: Qiao Yi-lun]

shrikes had fledged, several recorded instances of the care of juveniles being shared by more than one pair of adults were observed. Occasionally, unmated individuals of this species help in the task of brood-rearing, at times to the virtual exclusion of the breeding pair. Although co-operative breeding has been described for a few tropical members of the Laniidae, this seems to be the only example documented outside Africa.

Co-operative breeding, involving a breeding pair and a variable number of helpers, is practised by both of the *Corvinella* shrikes and both *Eurocephalus* species, as well as by at least one African species of *Lanius*, the Grey-backed Fiscal. Two sympatric species of *Lanius* were studied near Lake Naivasha, in Kenya, in an effort to understand the ecological factors favouring the evolution and maintenance of co-operative breeding. The co-operatively breeding Grey-backed Fiscal occupied territories having significantly greater tree and shrub cover than those occupied by the Common Fiscal, which is not a co-operative breeder; in addition, areas with greater vegetation cover held significantly more insects in the dry months of the year than did relatively open sites. Possibly associated with these differences in habitat and resources was a significant difference between the two species in the rate at which they disappeared during the study, population turnover among Grey-backed Fiscals being about half that of Common Fiscals. Similarly, territorial stability, as measured by the percentage of territories continuously occupied during the 18-month study, was nearly twice as high for the Grey-backed Fiscal. Within the restricted acacia (*Acacia*) woodland Grey-backed Fiscals were dominant over Common Fiscals, and in four instances the latter were observed to be driven out of their own territories by the Grey-backed Fiscals. It was suggested that co-operative breeding by Grey-backed Fiscals is related to occupancy of a stable but spatially restricted habitat of high quality; this may lead to relatively higher survival rates among Grey-backed Fiscals and, as a consequence, the habitat becomes "saturated" by the species. In such circumstances, juveniles have only limited opportunities for dispersal, and one evolutionary solution is that of group-living.

In the same Kenyan study, the roles of social and ecological factors in the maintenance of group-living were examined. Grey-backed Fiscals occurred in groups of 2–9 or more individuals, with only one breeding pair per group, the "supernumeraries" acting as helpers. The amount of perennial shrub cover in the habitat varied, and in the dry months areas with high cover contained significantly more prey items than did low-cover areas. Group size was positively correlated with shrub cover on three

of the four occasions during the three-year study when it was tested, and the average group size over an 18-month period was likewise correlated with shrub cover. Both individual survival and the number of young produced increased with increasing cover. Moreover, group size was correlated with these two factors of survival and productivity. Pairs or small groups of Grey-backed Fiscals occasionally colonized areas with poor vegetation cover, but, typically, these disappeared without having bred successfully. In contrast, high-cover areas harboured a constant number of breeding pairs and a varying number of supernumeraries. The latter appeared to have a choice between dispersal and remaining on the natal territory, the second option offering the probability that they would ultimately attain breeding status within or near the natal territory.

Male shrikes, in order to drive away rivals and to court females, sometimes execute a display in which they mimic the action of impaling prey. This is followed by courtship displays in which the male feeds the female and performs a bowing dance, as well as song and sometimes flight displays, about 7 m from the female. The female will accept prey from the male when she is ready to copulate, holding the food and lowering her upper body. Groups of neighbouring shrikes sometimes gather at the edges of territories and call at each other or perform dancing displays, behaviour which is thought to help in the establishing of pairs, as well as in reducing aggression and defining territories, thereby also indicating the location of vacant territories. Individuals may fight others in order to establish territories, but the marking of boundaries is usually done solely with vocalizations. Encounters with intruders involve bowing and fluttering displays, in which the body is held horizontal, the wings drooped and fluttered rapidly, the back feathers fluffed up, the tail spread and the head lowered, the shrike then pecking at the ground while uttering harsh calls. The rivals will face away from each other, and then whirl around to face each other and start the bowing again. If one does not retreat, a brief fight may ensue involving loud rasping calls, foot-grappling, and occasionally pecking.

Courtship feeding has been documented for a number of shrike species, and is probably a regular feature of the family. The provision of nutrients by a male can increase the female's reproductive success, and males can, therefore, use such gifts to influence female choice. Polish researchers investigated courtship feeding by Great Grey Shrikes. It was found that the males offered food both to their mate and to extra-pair females, and that food offered to the latter had a significantly higher energy value than did that offered to their own partners. There are, how-

Shrikes are skilled hunters, and sometimes capable of tackling prey up to their own body size.

In some species, individuals are known to have killed territorial rivals and impaled them in thorny larders. In others, individuals have been observed catching unrelated bird species, often in flight. The number and variety of birds hunted by shrikes is astonishing, but most reports involve small passerines. This Great Grey Shrike is carrying what looks like a sparrow (Passer).

One of the most famous attributes of shrikes is their habit of caching prey items by impaling them on thorns at traditional sites in the territory. This **Red-backed Shrike** is attending a typical shrike "larder", with one beetle and one male wall lizard (*Podarcis muralis*). The functions of this behavioural trait are unclear, but they may have something to do with mate attraction or reproductive success. For example, it is possible that females choose mates on the basis of how much food they have been able to stockpile, or that a well-stocked larder allows breeding pairs to invest more time and less energy in incubating or provisioning the brood.

[*Lanius collurio collurio*, Ariège, France.

ever, very few definite examples of courtship feeding prior to extra-pair copulations. The size of the prey being offered to a female may enable her to assess a male's quality. The observations revealed that a larger gift resulted in a higher chance of copulation for the male, whether with its own mate or with an extra-pair female, and it was concluded that the energy value of additional food received through courtship feeding by males could explain why females of some species engage in extra-pair copulations.

Ornithologists studying Red-backed Shrikes in Sweden found that courtship feeding had an influence on clutch size. Males, through courtship feeding, directly influenced the number of eggs the females laid, but the mechanism behind the female response is at present unknown. In Japan, however, the rate of courtship feeding by Bull-headed Shrikes was not associated with copulation, but was most frequent in the cold season, during the critical stages of egg-laying and incubation. This suggests that it is important for the early breeders in that it helps the female to build up reserves while the ambient temperature is low and food is scarce.

Most shrike species hold all-inclusive and non-overlapping breeding territories within which mating, foraging and brood-rearing take place. Territory size varies according to the species, and also in relation to such factors as population density, habitat characteristics and resource availability. Males attract mates through song and through the maintenance of large food caches (see Food and Feeding). These stores often include colourful inedible items, presumably to increase their attractiveness to possible mates. Males with more prey in their caches attract more females, and their mates generally lay more eggs and fledge more young than those paired to males with smaller larders.

In studies of Loggerhead Shrikes carried out in Canada, the average size of territories in south-east Alberta, at the northern limit of the species' range, was 8.5 ha. Although there were small differences from one year to another, territory sizes did not differ between the incubation and nestling periods. Territories were larger than those in more central parts of the range, probably because the region is more arid and prey fewer in number.

An important characteristic discovered in recent years is that shrikes appear to "clump" their nests in certain areas, as was found, for example, with Loggerhead Shrikes in Oklahoma. A statistical analysis of Loggerhead Shrike territory distribution

produced some interesting findings. When the data were examined without regard paid to the dates of nest establishment, the results were equivocal. When the times at which nests were established were taken into account, however, the later ones were far more likely to be closer than expected to pre-existing nests of conspecifics. This was true even when the distribution of resources such as suitable nest-sites was included in the analysis. Similarly, in Idaho, Loggerhead Shrikes usually nested in proximity to others of the species, even in large areas of sagebrush, and this was thought possibly to offer additional awareness of nearby predators and/or to increase the ability of individual shrikes to find mates. These findings support the hypothesis that Loggerhead Shrikes, when looking for suitable breeding habitat, are guided by and base their selection on the distribution of breeding conspecifics. This clumping of nests has been reported also for the Red-backed Shrike across much of its distribution, the Brown Shrike and Bull-headed Shrike in Japan, and the Common Fiscal in South Africa.

Predation is possibly an important factor affecting an individual's behaviour and general life, but few studies have focused on the question of whether predators affect the prey species' selection of breeding habitat. A study in Sweden tested whether breeding-habitat selection and reproduction by the Red-backed Shrike were linked to the presence of breeding pairs of the shrike's potential nest predators, which were the Eurasian Magpie (*Pica pica*), the Hooded Crow (*Corvus cornix*) and the Western Jackdaw (*Corvus monedula*). An artificial experiment with nests mimicking those of Red-backed Shrikes indicated that only Eurasian Magpie and Hooded Crow territories were associated with an elevated risk of predation. Among Red-backed Shrike nests in the wild, the predation risk was likewise greater for those close to nests of these two predator species than it was for nests elsewhere in the landscape. Occupation frequency of known Red-backed Shrike territories during the study increased with increasing mean distance to the nearest magpie nest. In addition, changes in the spatial distribution of corvids affected the spatial distribution of the shrikes. It was found that vacant Red-backed Shrike territory sites were more likely to become occupied in the following year when Eurasian Magpies and Hooded Crows had moved away, and, conversely, occupied sites were more likely to be abandoned in the following year when crows had moved closer. The evidence indicates that the breeding territories of nest predators may,

Whether shrike larders are sophisticated foraging adaptations or sexual signals is debatable, but the act of impaling prey seems relatively straightforward to explain in terms of evolutionary origins. It probably arose because it solves a simple mechanical problem, namely prey handling. Shrikes have trouble manipulating vertebrate prey because their bills and feet are relatively small and weak compared with other raptorial birds. Thus, impaling helps to "anchor" vertebrates so that they can be more easily dismembered and eaten. As if to demonstrate this idea, a **Southern Grey Shrike** is able to break up a small rodent into bite-size pieces using only a handy thorn. One outcome of prey caching is parasitism: shrike larders are often raided by neighbouring pairs, or even by other avian predators such as owls or falcons.

indeed, have an influence on the breeding-habitat selection of their prey.

Intensity of nest defence increases as the breeding cycle progresses. An example is that of the Red-backed Shrike, which protects its nest aggressively, attacking predators and potential predators which approach the site. In one study, this shrike, in response to the presence of a human observer during the nesting period, became increasingly bold in its defence. The level of aggression was not, however, influenced by the number of offspring present and the time of the season, and, contrary to previous predictions, the researchers did not find any differences between the sexes in nest defence. More aggressive parents, both females and males, had significantly better breeding success than did calmer individuals.

Nests of shrikes are generally large, untidy, uncamouflaged structures, normally incorporating a variety of materials, including man-made ones, found in the breeding pair's territory. The two *Eurocephalus* species and Souza's Shrike (*Lanius souzae*) are exceptions in that their nests are small, neat, well-moulded and camouflaged, the construction and general positioning being much more reminiscent of nests of the malaconotid genus *Prionops* than of those of the *Lanius* species. Laniid nests are almost always built in thorny bushes or small trees, in hedge-rows or in the outer parts of tall trees. There are reports also of nests being placed in strongly entangled barbed-wire rolls, and one nest of a Lesser Grey Shrike was situated at the bottom of a cavity 38 cm deep. Nests are often built one or two metres above the ground, and it seems that the exact site is selected on the basis of structural aspects of the vegetation cover, and not the plant species themselves.

Both sexes gather nest material, but it is generally the female that does the construction work, taking 6–12 days to complete the task. The size of the finished nest is variable, but nests are roughly 15 cm in outside diameter, 10 cm in internal diameter, and 7.5 cm deep. In general, they are tightly woven, bulky, open cups lined with soft material. The nests usually consist of large pieces of vegetation, such as twigs, forbs and bark, with rootlets added; the lining is highly variable, including such items as flowers, lichens, grasses, moss, feathers, fur, cattle hair, string, cloth and the like. Even so, shrikes are able to alter their nest-building behaviour to suit the immediate surroundings. Typically, the nest is very well insulated, with a low level of thermal loss, this being a possible adaptation to cool, wet weather.

Nests may be reused from year to year, but it is more common for the old nest to be dismantled and the materials used for a new one nearby. When re-nesting occurs in the same season, as may occur, for example, after a failed attempt, shrikes generally tend to nest higher above the ground on their second attempt. A study in Germany looked for possible reasons why Red-backed Shrikes did not conceal their nests better. Altogether 296 nests were categorized for degree of visibility from distances of 1 m and 2 m from above and on all four sides of the nesting bush or tree. Almost half of the nests, 47%, were exposed and only 16% were well concealed, and the number of exposed nests increased as the breeding season progressed. The nests are easily detectable by predators, whether foraging actively or by accident, and concealed nests indeed had higher breeding success. The authors of the study considered the findings to reflect the lack of better alternatives in the changing habitat and limited potential nesting sites. For Red-backed Shrikes in Germany, a precondition for the establishment of a territory was the existence of vegetation suitable for nest-building. Shrikes preferred to build nests at heights of 0.8–1.6 m. The importance of the quality of the nesting bush or tree is underlined by the fact that, besides weather and predation, losses occur owing to inadequate attachment of the nest or weakness of the supporting branches, resulting in 7.5% of the nests slipping or tipping over.

In Estonia, nest-card data for the years 1942–2001 revealed that Red-backed Shrike nests had been found in 41 different plant species, but 41% of all the nests were in spruces (*Picea*). The average height of the nest tree was 2.8 m and the average height of the nest placement was 1.2 m; there was no difference in the average nest height between successful and unsuccessful pairs. On Hokkaido, in north Japan, Bull-headed Shrikes nested in dwarf bamboo and vine bushes in the early part of the breeding season, and, as the season progressed, moved their nest-sites to a variety of deciduous shrubs as the foliage load of these plants increased. Nest height increased gradually throughout the breeding season, an observation that was attributed to seasonal changes in the use of vegetation types. Thus, Bull-headed Shrikes exhibited a seasonal change in nest-sites with the progress of plant phenology, and this reduced the risk of nest predation.

In North America, the Loggerhead Shrike is a widely distributed member of Idaho's sagebrush-rangeland avifauna. In a study of its breeding ecology and nesting locations in this semi-arid habitat, most nests, 65% of those found, were constructed in

Shrikes produce a lot of pellets containing indigestible material such as mammal fur or insect chitin. These pellets have proved to be a boon for researchers because they offer a window into foraging behaviour and diet. Pellet analyses of the **Loggerhead Shrike**, for example, have shown that a population on one South Carolina island had a diet comprising 17.1% earwigs (*Dermaptera*), 13.9% ants (*Formicidae*), 13.1% crickets, 8.7% grasshoppers, and 6.7% side-blotched lizards (*Uta*).

sagebrush. The height of the nest shrubs was 0.89–2.97 m, the average being 1.62 m, and the mean height of nests was 0.79 m, with the range 0.33–1.60 m. The nest variables measured did not differentiate successful nests from unsuccessful ones. Nests constructed in dense greasewood shrubs contained fewer medium-sized and large sticks, typically used in construction of the nest substructure, than did nests built in relatively open sagebrush; in contrast, there was no difference in the quantity of lining fibres, twigs and small sticks used in nests constructed in these shrubs. These findings could be due to the different nest-stabilization requirements imposed on the shrikes by structurally dissimilar nesting substrates, and suggest a degree of plasticity in the nest-building behaviour of the shrikes. In another part of the Loggerhead Shrike's range, in central Missouri, success was highest for nests in deciduous trees and lowest for those in multiflora rose (*Rosa multiflora*), possibly because rose bushes are not so structurally sound nor so thorny as those deciduous trees used for nesting. In south-central Washington nests having better concealment produced more fledged young, and in Minnesota nesting success was positively correlated with the percentage cover of grassland and fledging success with percentage cover of herbaceous vegetation and of grassland. In Manitoba, nest-sites with lower amounts of understorey (ground cover and vegetation height) were more successful, and nests in pasture were more productive than were those in cropland or in mixed habitat types.

In Idaho, the breeding density was one pair per 8.9 ha in an isolated 89-ha stand of sagebrush and bitterbrush, with an average nearest-neighbour distance of 203 m; in the same general area, it was one pair per 25 ha in a rugged 475-ha bowl of sagebrush and the average distance to the nearest neighbour was greater, at 328 m. The disparity was attributed to habitat characteristics, as the average shrub height was greater at the site with smaller territories.

Clutch size varies with latitude. Large clutches, containing 7–9 eggs, are laid at high latitudes and small clutches, of 2–3 eggs, are normal in the tropics. If the first clutch is lost, however, a comparatively smaller replacement is laid. From historical records, the average reported clutch size for Loggerhead Shrikes is 5.4 eggs, with a range of 1–9 eggs; 36% of clutches contained six eggs and 34.2% had five eggs, and at the two extremes only 0.4% were of one egg and 0.1% of nine eggs.

Eggs are laid usually in the early hours of the morning, one per day over the course of a week or so. Shrike eggs tend to be variable in colour and pattern. For example, those of the Red-backed Shrike are smooth and oval, with a ground colour varying from pale green to pinkish, buff or creamy white, and with a band of light brown, olive, brownish-red, grey or purple speckles and small blotches near the broad end or, sometimes, with the markings scattered over the whole surface or even, unusually, present only at the narrow end. The eggs of Souza's Shrike are pale green-grey, with grey, brown and purple freckles around the broad end; they seem to lack the blotching typical of other *Lanius* species.

Despite numerous studies of bird eggs, the function of egg-shell patterning remains largely unknown. Possible functions include the signalling of condition, and mimicry. It has been suggested that eggshell patterning, as well as egg size and shape, might be linked to natural selection. Description of egg variability and its causes among Loggerhead Shrikes could be particularly important, because of this species' wide distribution in North America and the uncertainty over the reasons for its population decline.

It has been postulated that egg size could be affected by climate change. During the period from 1971 to 2002, in a long-term study of Red-backed Shrikes in Poland, it was evident that egg volume decreased significantly, the shrikes arrived at the breeding sites significantly earlier, and arrival dates were correlated with the earliest first-egg dates. It was tentatively suggested that the causes of these changes might include, among other factors, changes in temperature and also in food supply, although further studies are required.

Although the mean volume of Bull-headed Shrike eggs in Japan did not change during the course of a season, the variation in volume in six-egg clutches increased in 1994 and 1995 but did not change in 1996. Peaks in arthropod biomass occurred

early in the breeding seasons in the first two of these years, but late in the season in 1996. Increased food availability was associated with reduced variation in egg volume within a clutch. A significant difference in egg size was found within six-egg clutches, the first egg being the smallest. Nevertheless, chicks that hatched from small eggs early in the hatching sequence suffered lower mortality rates than did those from large eggs laid late in the order. It was suggested that egg-size variation within a clutch was perhaps caused by a trade-off between the time required to develop an egg and the volume of the first egg within a clutch. Because eggs hatching first in sequence do not have to be large for the hatchling to survive, the Bull-headed Shrikes may start to lay the clutch earlier at the cost of reducing the volume of the first egg.

Incubation normally starts from either the last egg or the penultimate one. Females incubate while the males forage, but females generally lose weight during the period of incubation, which lasts for about 15–20 days. During this period the females turn the eggs 6–10 times daily, and often more frequently on hot days.

Hatching is typically synchronous, except in cases when incubation was started before the full clutch had been laid. The sequence in which the eggs in a clutch hatch matches the order in which they were laid, the first-laid also being the first to hatch. Hatchlings are altricial, being blind and helpless and usually naked. They vary somewhat according to species, but in very general terms they have pinkish-orange skin and a yellow or orange-yellow mouth lacking spots. On the first day their weight is in the approximate range 3–7 g, and they gain some 3 g or more daily until the twelfth day; growth then slows until the time of leaving the nest, generally between days 17 and 21, when they weigh roughly 40 g. The wings have developed fully by 15 days. The rate at which the parents deliver prey to the nestlings increases from day 6 to day 12, thereafter decreasing until just before the young leave the nest, when it reaches a peak. In the first 4–5 days, the female feeds the young with food presented to her by the male, but after this she normally spends more time in foraging and less time in brooding, while her mate feeds her less and starts to provision the chicks directly.

Many aspects of the begging behaviour of nestlings relate to sibling competition for food within the nest, and one could expect the chicks to exhibit some evidence of adaptive learning and behavioural adjustment in response to experience of the competitive environment. Researchers conducted trials involving the

Shrikes usually produce pellets while foraging or resting, and disgorge them from an elevated perch, as demonstrated by this male **Brown Shrike**. This species is common in East Asia, a region where shrikes have radiated into an impressive variety of species. It breeds from Mongolia and Siberia, to China, Korea and Japan, with non-breeding populations wintering south to Sri Lanka, the Malay Peninsula, and the islands of Sumatra, Java, Borneo, Sulawesi and the Philippines.

[*Lanius cristatus superciliosus*, Hegurajima, Ishikawa-ken, Honshu, Japan. Photo: Hirozo Maki]

Most shrikes breed in monogamous pairs and use fairly modest courtship displays. These displays sometimes involve mock food-impaling or a bowing dance by males, but the most obvious intra-pair behaviour is courtship feeding. Males in many shrike species provision females during the breeding cycle. Studies of the **Bull-headed Shrike** have shown that courtship feeding is most frequent, not prior to copulation, but during the critical stages of egg-laying and incubation. In the courtship phase, the food offered is freshly caught, but when the female is incubating or brooding, the male visits his larder of stored prey to supplement the items brought to the nest.

[*Lanius bucephalus bucephalus*, Itako-si, Ibaraki-ken, Honshu, Japan. Photo: Hirozo Maki]

hand-feeding of Southern Grey Shrike nestlings in an artificial nest, in which they created zones of differing profitability by adjusting either the prey size or the number of food items delivered. The chicks did, indeed, detect the differences and positioned themselves accordingly; by the end of both the prey-size experiment and the delivery-rate trial, the nestlings had increased the amount of time that they spent in the "high-quality zone".

In a study of Bull-headed Shrikes in Ishikari, in northern Japan, seasonal changes in the relationship between brood size, the body mass of nestlings and the body mass of parents were investigated. When broods were twelve days old, the body mass of the heaviest nestling in a brood did not differ with brood size, or throughout the season. The body mass of the lightest nestlings, however, varied according to brood size, and the body mass of the lightest nestling in broods of five and six chicks decreased throughout the season. The lightest nestling in four-chick broods and the lightest and second lightest in five-chick broods had weights significantly lower than that of the heaviest nestling in broods of these sizes. It is likely that shrike pairs with six 12-day-old chicks in the nest can feed at least five of these sufficiently to ensure their survival. The standardized body mass of the parents, defined as the mass divided by the length of the tarsus, did not vary with brood size or with time of the season. The researchers concluded that this constancy, coupled with the seasonal decline in the body mass of nestlings, might indicate that Bull-headed Shrikes have a limit to their parental efforts.

In a study of the body constituents of nestling Red-backed Shrikes in Poland, it was found that, as the chicks became older, the percentage content of protein and fat increased and that of water decreased. The bioenergetics of nestlings are of great interest because of the chicks' fast growth rate, which is dependent on brooding and feeding and may limit brood size. Of 13 broods containing a total of 59 nestling Red-backed Shrikes in Poland, two stages in the nestling period could be distinguished, the first from hatching to 7–8 days of age and the second from 7–8 days to fledging. In the first stage, nestlings have no effective thermoregulation and are brooded by the parent; this allows them to develop under presumably optimal temperatures, and to use most of their assimilated energy for rapid growth. During the second stage, the chicks have effective thermoregulation and brooding is very limited; a large proportion of assimilated energy is then

used for heat production, and the rate of growth decreases. The development of plumage, an increase in body size, and huddling with nestmates prevent excessive heat loss. The chicks' highest energy requirements were in the middle part of the nestling period, and, if conditions were then unfavourable, this period could limit the brood size.

After fledging, the young shrikes remain in the nest tree or bush for a few days before flying to other perches. They perch in heavily foliated trees or in undergrowth, very close together, and they keep quiet, begging for food only when the parents arrive. About one week after leaving the nest, they are able to fly increasing distances, and they begin to follow the parents in order to learn hunting skills. The young remain dependent on the adults for 3–4 weeks after fledging, and they then begin to forage on their own successfully. They begin to perform impaling movements at 20–25 days of age, and can impale food items successfully at 33–35 days, but it is not until they are 40 days or so old that they have fully developed the ability to attack and kill vertebrate prey.

A notable aspect of parental behaviour observed in the Negev Desert of Israel was that of the mother transferring the nestlings to a different place. This was discovered by accident when, at four nests of Southern Grey Shrikes, the entire broods disappeared immediately after having been colour-ringed at the age of 10–13 days. All of the young were subsequently found at the base of different bushes at distances of 3–55 m from the nesting tree or bush; each brood was clumped together in a cavity excavated on the ground and concealed by dense vegetation. The female was seen to prod each individual nestling out of the nest and on to the ground, and then to coax it to the alternative hiding place. During the process the male remained perched in the vicinity, keeping a watch for potential predators. Similar behaviour was reported for Loggerhead Shrikes in Idaho, where the parents were observed to induce nestlings to leave the nest earlier than they would naturally have done. This appears to be the reaction of the parents to human disturbance or to possible discovery of the nest by a predator, and was substantiated by the fact that it was observed at a nest that was partially preyed on by a diadem snake (*Spalerosophis diadema*) and, elsewhere, after a Common Kestrel perched on the nest tree. It appears that the translocation can be made only when the nestlings are sufficiently developed that they do not require brooding. The high ratio of such nestling trans-

Pairs of **Red-backed Shrike**, a widespread European breeding species, arrive from their African wintering quarters each spring to set up territories in a variety of shrubby habitats. Once the territory has been established, the male will contribute to the collection of nesting material, but in most cases the bulk of construction duties fall upon the female. The nest structure contains a wide variety of plant materials, including grasses, twigs, moss, and—in this case—strips of bark. In total, it takes 6–12 days to build.

fers suggests that the strategy has adaptive advantages, and that it allows an increase in fledging success that would not be possible if young were left at the nest once discovered by the predator. This behaviour was observed also for Bull-headed Shrikes in Japan and Red-backed Shrikes in Belgium.

Brood parasitism by cuckoos and others also takes place. Red-backed Shrikes in Hungary were parasitized by the Common Cuckoo (*Cuculus canorus*) at a low frequency until the late 1960s, but since then there have been no confirmed cases of parasitism in that country. It seems probable that the cuckoo abandoned this host species because it lost the so-called "arms race", which may be indicated by the shrike's high level of the egg recognition. Experiments showed conclusively that Red-backed Shrikes are able to recognize their own eggs and reject the parasite's eggs. Although this shrike was a host of the cuckoo in the past, it learned to identify accurately the parasitic eggs; the cuckoo, rather than evolving perfectly mimetic eggs to counteract the host's recognition ability, switched host species.

In Germany, no cases of successful nest parasitism were found in a population of Red-backed Shrikes intensively studied for 20 years, during which time more than 1200 nests were monitored. In 1978, three of 22 nests contained young cuckoos, but all three of these broods were unsuccessful because of inclement weather and predation. It was noted that one of the cuckoo nestlings was unable to eject the eggs of the host. In another study, in the eastern Moravian region of the Czech Republic, a total of 45 young Common Cuckoos was found in a total of 2681 Red-backed Shrike nests. Here, the annual proportion of parasitized nests ranged from 0% to 5.5%, the average for the rest of the Czech Republic being 0.5% in 2949 nests. Again, the impression is that the cuckoo appears not to be responsible for any significant reduction in the shrike's breeding capability. In Japan, the frequency of parasitism of Brown Shrike nests by Common Cuckoos on Hokkaido was very low, and the shrikes either removed the cuckoo egg or deserted the nest containing it.

Little is known about the frequency of brood parasitism by Brown-headed Cowbirds (*Molothrus ater*) on Loggerhead Shrikes in North America. The cowbirds opportunities to parasitize shrike nests may be limited owing to the Loggerhead Shrike's aggressive and predatory nature. In fact, only two documented cases of brood parasitism have been recorded: three of 261 nests in south-

west Iowa and two of 1661 nests in Manitoba were parasitized. Experimental attempts to parasitize Loggerhead Shrike nests met with limited success; the shrikes rejected Red-winged Blackbird (*Agelaius phoeniceus*) and Tricoloured Blackbird (*Agelaius tricolor*) eggs that were placed in shrike nests.

Two crucial aspects of fecundity are the age of first breeding and the reproductive output. As with most other songbirds under good conditions, shrikes start to breed in the first spring following the one in which they hatched. Breeding productivity is dependent on a variety of factors, and some examples are given in the paragraphs below.

Food abundance influences various aspects of a bird's breeding ecology, such as the timing of laying, the clutch size, and the success rate. A team of European researchers examined the effects of a natural superabundance of food, in this case cockchafer (*Melolontha melolontha*), on the nesting success of a monogamous long-distance migrant, the Lesser Grey Shrike. In years of cockchafer outbreaks, these beetles make up 88% of the adult diet and 48% of the nestling diet of this shrike. The researchers compared the timing of egg-laying, clutch size and fledging success in three years and chick development in two years, incorporating years with cockchafer outbreaks and years without. In "cockchafer years", laying dates were about one day earlier, clutch size increased by about one egg, and heavier chicks were produced. Fledging success, however, was unaffected, because more eggs failed to hatch during cockchafer years. Increased clutch size in periods of superabundant food did not, therefore, always result in an increase in fledgling production. The team concluded that, in the study population of Lesser Grey Shrikes, limited incubation ability of the adult shrikes or intrinsic problems in physical egg properties, resulting in inefficient incubation, were the most likely explanations for the increase in hatching failure in years with a superabundance of food.

A long-term, 30-year study of the Red-backed Shrike population in south-west Germany found that pairs produce an average of 2.84 fledglings per year, productivity varying between 1.9 and 3.9 fledglings per pair. Years with low breeding success are almost always those with inclement weather, and even brief cold spells, which occur regularly in June, lead to heavy nest losses. In addition to breeding success, the survival of the adults of this migratory species is clearly of critical importance. In the three

Shrike nests are generally large, loosely woven, cup-shaped structures built from a variety of materials, including man-made objects. That of the **Masked Shrike** is typical in being plastered with bits of lichen, bark and wool. It is usually situated 1-2 metres above the ground on top of horizontal branches, or in a fork between upright branches. Like most shrike nests it is balanced on branches, rather than woven into place, and it tends to be very poorly camouflaged. Although males and females often forage independently, they regularly consort at the nest-site throughout the breeding cycle.

[*Lanius nubicus*,
Cyprus.

decades of the study, no change has been detected in the return ratio of adults in consecutive years. In the Karlovy Vary region of the Czech Republic, a comparison of Red-backed Shrikes breeding at two different altitudes, 450 m and 650 m, revealed no difference in the dates of nest initiation and egg-laying, nor in clutch size; breeding success was 77% at lower levels but only 62% at higher-lying sites, because predation was much greater at the higher elevations.

In recent decades, the Brown Shrike has undergone a severe decline on Hokkaido, in north Japan, and a study of the reproductive performance and nestling growth was therefore undertaken. During 1992–1996, 41 active nests were examined, and the mean nesting success was found to be 53.7%. The average clutch size was 5.3, and the average number of eggs hatched per nest was 5.1; successful nests produced an average of 4.4 fledglings each, giving a mean fledging success per successful nest of 90.3%. The main cause of nesting failure was identified as predation, but the identity of the predators was unknown.

Average nest success of Loggerhead Shrikes across North America was reported as 56%. In Oklahoma, the probability of survival from the start of incubation until fledging was 46%, which is low compared with the findings of studies in other areas, but the percentage of Oklahoma nests that produced fledglings was somewhat higher, at 59.5%. Furthermore, nest success at any one site can vary greatly from one year to another, as demonstrated by a study in Missouri, where success decreased from 82.1% in 1980 to 55.5% in 1981. The average number of fledged young per nest varies from less than one to more than four. Mortality in the period from fledging to independence is rather high; for example, 46% of young died during the first week after fledging in Indiana, 33%–53% were lost during the first ten days after fledging in southern Alberta, and mortality of 33% from fledging to independence was recorded in Virginia. In western shrub-steppe communities, average survival decreased from 5.1 young per nest at the time of fledging to just 2.3 two weeks later; similar results were found in Ontario, where the corresponding figures were about four young per nest at fledging and 2.5 when the young became independent.

Most Loggerhead Shrikes of the migratory subspecies have single broods and reneest only after failure with the first attempt. The sedentary populations, however, raise up to three broods per

year, this depending largely on climate, where warmer and longer growing seasons result in more broods. Further, non-migratory shrikes are more likely to attempt second broods, and high nest success increases the probability of additional nesting attempts.

In Africa, in a study of Common Fiscals, young fledged from only 15% of the nests found. Of the 17 breeding pairs studied, only eight produced any young, at an average of 1.9 fledglings per nest.

Various studies have revealed that productivity and breeding success of Red-backed Shrikes in central Europe are reduced in years with wet and cold weather. The same has been found to be true for Loggerhead Shrikes in North America, Great Grey Shrikes in Poland and Southern Grey Shrikes in Israel. Inclement weather in Japan in 1993 allowed comparison, with 1992, of the effects of weather conditions on aspects of the Bull-headed Shrike's breeding biology, such as the timing of breeding, nestling growth and overall nesting success. For both years, the season was divided into two periods, early and late. While the probability of nestling survival was almost the same during both periods, the probability of nest survival in the egg stage during the early period was significantly lower than that during the late period. In 1993, nestling survival during the late period was significantly less probable than during the early period; the late period was colder than the same period in 1992, and with larger fluctuations in precipitation. The number of "lost" nestlings was positively correlated with the mean daily precipitation, and most were the lightest in weight in each brood. It was found that the late breeders fledged lighter young than did the early breeders. Although the shrikes adopted hatching asynchrony, the late breeders could not overcome the effects of the unpredictable adverse weather in 1993.

In contrast, predators were the most important factor in determining the breeding success of Woodchat Shrikes in Spain. It was estimated that predation reduced breeding success by an average of 35% annually. In Mediterranean France, this species' breeding habitats consist of open, dry grassland with a discontinuous short-grass layer and scattered bushes and trees, where about 75% of the Woodchat Shrike's nests were at heights between 1 m and 3 m. The mean survival rate of nests from laying to fledging was 36%, and there was no correlation between breeding success and the site, height and concealment of nests. The main cause of the low breeding success was, again, a high rate of

nest predation. Woodchat Shrikes in the El Kala National Park, in north-east Algeria, nested most frequently in cork oak (*Quercus suber*), at a mean height of 5 m. First clutches were laid on 7th May, about the same as in south France, and average clutch size was 4.9 eggs, slightly less than in France. Approximately 42% of eggs in Algeria produced fledglings. In this case, fledging success was positively correlated with the height of the nest above the ground, as well as with mean egg size of the clutch. It was suggested that heavy predation and poor food availability were probably the major selective pressures shaping the life history of Woodchat Shrikes in Algeria.

A most interesting phenomenon is that of a breeding association between shrikes and other species. Such associations are known to occur between the Red-backed Shrike and the Barred Warbler (*Sylvia nisoria*), the Isabelline Shrike and the Barred Warbler, and the Woodchat Shrike and the Orphean Warbler (*Sylvia hortensis*). In southern France, active nests of both Woodchat Shrikes and Orphean Warblers have been found in the same bush, and this, along with behavioural evidence, suggests that the association goes far beyond being a simple commensalism for the sole benefit of the warbler. It may be considered, instead, an example of mutualism designed to counter the problem of predators, but its precise extent evidently requires further observations. In North America, on the other hand, it was discovered that shrikes could exercise a significant control on the distribution and numbers of passerines in their breeding areas. In one study, Loggerhead Shrikes were observed while feeding on the nestlings of other passerines, resulting in the probable nest loss for the latter. This suggests that, although birds comprise only a small percentage of the shrike's annual diet, the timing of predation on passerines could result in a marked negative effect on the annual production of the passerine community. One must, however, consider other factors, including the broader interactions of predator-prey relationships, competition and habitat structure. For instance, if short vegetation and a greater density of perches lead to an increase in shrike presence and, at the same time, a decline in the broader bird community is detected, this decline is not necessarily attributable to shrikes; the increased number of perches may attract higher numbers of raptors, which could have a negative impact on the entire bird community, including, ultimately, shrikes, through increased predation and competition. Clearly, a great deal of additional research is required before a proper understanding can be gained of the impact of shrikes on the bird communities of which they are a part.

Conversely, prey populations are known to have a direct influence on shrike populations. As would be expected, decreasing abundance of such prey as insects and small mammals leads to the reduction or even the elimination of local shrike populations. Furthermore, predation by other animals is, for shrikes, often the greatest cause of nest failure, although it is not known if this has serious impacts at the population level. In addition, various other birds attack recently fledged shrikes without killing them. In America, for example, young Loggerhead Shrikes are attacked by, among others, Scissor-tailed Flycatchers (*Tyrannus forficatus*), American Robins, Eastern Meadowlarks (*Sturnella magna*), Common Grackles (*Quiscalus quiscula*) and Brown Thrashers (*Toxostoma rufum*). In return, shrikes will harass other passerines, especially during territory establishment, when the shrike often chases the other from its own territory, sometimes causing other birds to move out of the immediate area.

Survivorship of adult shrikes is uncertain. In Oklahoma, a Loggerhead Shrike was recaptured after 11 years, in the same general area in which it had been ringed. Other ringed individuals have been documented as living for six years and more, but there are few data on longevity of laniids. It has been suggested that mortality in the non-breeding areas is the reason for observed reductions in abundance of some species, a possibility which is supported by the low return rates of first-year shrikes. Low return rates, however, cannot be taken as evidence of high winter mortality without considering breeding-site fidelity. In all studies of migratory *Lanius* species, the percentage of juveniles returning to the natal site to breed is very low, which suggests that there is a high rate of exchange of individuals between different populations.

In a colour-ringed population of Common Fiscals, the annual survival was 39%. Since 25% of the adults were known to have resided in two or more territories, however, this is probably an overestimate of mortality because of dispersal out of the study site.

Movements

Whereas many members of this family are resident, some shrikes undertake long-distance intercontinental migrations of several thousand kilometres each year. Red-backed and Lesser Grey Shrikes migrate more than 10,000 km between their Eurasian breeding grounds and their respective wintering areas in sub-Saharan Africa, and Lesser Grey Shrikes breeding in north-west China may travel nearly 12,000 km to non-breeding grounds in Namibia. In eastern Asia, the Brown Shrike covers a distance of up to about 8000 km between its Siberian breeding quarters and its non-breeding grounds in the southern parts of Asia.

In the Afrotropics, the movements of the two wholly African genera, *Corvinella* and *Eurocephalus*, are not well known. It seems that some seasonal movements are made, and occasional nomadic movement occurs. The Yellow-billed Shrike shifts southwards in the dry season, returning north with the rains; it is sometimes seen in large flocks. Its congener, the Magpie Shrike, is thought to make similar dry-season movements in, for example, north Namibia and central Zambia, and occurs as a rare visitor in south Malawi. The Southern White-crowned Shrike appears to be strongly nomadic and rather irruptive in years of drought, and it may also undertake some seasonal movement. Similarly, Northern White-crowned Shrikes possibly make some local seasonal movements, but little information is available for this species.

Lanius species in tropical and subtropical areas are generally resident. They have little need to migrate, as their food supply is fairly constant throughout the year. In contrast, those shrikes breeding in the northern parts of the family's range are mostly long-distance migrants, and this is especially important for the smaller, insectivorous laniids. The availability of invertebrate prey, of course, is normally seasonal at higher latitudes, and insecti-

Incubation in shrikes begins with either the last or the penultimate egg. This ensures that hatching is usually more or less synchronous. Breeding females often take sole responsibility for incubation, which lasts about 15–20 days. Even in the group-living Magpie Shrike, only one bird incubates, the dominant female. She is fed during this period by her mate, and by one or more helpers. As with other shrike species, she rarely strays from the nest, only moving to turn the eggs 6–10 times daily, and perhaps more frequently on hot days.

[*Corvinella melanoleuca melanoleuca*, Nylsvley, South Africa. Photo: Warwick Tarboton/VIREO]

This image shows a male **Common Fiscal** passing the female a prey item, which she accepts without leaving the nest. Despite regular provisioning of this kind, female shrikes tend to lose some weight during the incubation period. Occasionally, male Common Fiscals take over at the nest for brief periods, but in many pairs the female appears to do all the incubating. The nest of this pair is a classic shrike creation, a bulky, untidy cup built loosely from natural and artificial items. In this case the structure consists of grass, twigs, rootlets, animal hair and string.

[*Lanius collaris smithii*,

vores are forced to migrate after the breeding season. Not surprisingly, therefore, the Red-backed, Isabelline and Brown Shrikes, as well as the Tiger Shrike (*Lanius tigrinus*) of east Asia, are long-distance migrants. Similarly, the Woodchat and Masked Shrikes (*Lanius nubicus*), which breed in the Mediterranean region, and the Lesser Grey Shrike, which extends from the north Mediterranean eastwards to Central Asia, feed mostly on invertebrates, and all three are migratory. On the other hand, larger laniids, as typified by the Chinese Grey Shrike, the Great Grey Shrike and the Loggerhead Shrike, are capable of catching small vertebrates, and they can, therefore, to varying degrees adapt to the difficult weather conditions of the winter months, so long as vertebrate prey is still accessible. This means that the northernmost breeders often move southwards when conditions become too difficult, whereas those in more southerly parts of the range are residents.

The Laniidae do not build up large fat reserves prior to migration, and it is assumed that this is because of their ability to exploit exhausted passerines as a food source while on active migration. The shrikes themselves, however, are also heavily preyed upon during migration, this being due chiefly to their relatively straight and comparatively slow flight. As an example, a large proportion of the prey of Eleonora's Falcon (*Falco eleonora*) consists of shrike species migrating across the Mediterranean Sea. From an estimated 100,000 prey items identified, 4% were Woodchat Shrikes, 8% Lesser Grey Shrikes and almost 11% Red-backed Shrikes.

In a ringing study of migrant Brown Shrikes in Peninsular Malaysia, it was discovered that this species migrates by night and on a broad front, descending during the day. The data obtained from a decade or so of ringing indicate that these shrikes arrive at more or less the same time in all parts of their non-breeding grounds in tropical South-east Asia, and that they make the journey from the breeding grounds comparatively rapidly. The fact that passage migrants in Taiwan had an average body mass of 31.7 g, whereas those in Malaysia weighed 28.2 g, suggested that Brown Shrikes depend on fat and muscle reserves for the migration, and that they do not depend only on prey caught along the migratory route.

The Loggerhead Shrike's migration is not well understood. Populations breeding in the northern parts of the range are gener-

ally migratory, moving into the southern states and Mexico during the winter. All of those breeding in areas south to Wyoming, central Colorado, Kansas, Missouri and roughly north of Kentucky are migratory, as also are those in northern California, north Nevada and north Utah. Other parts of the southern USA are home to resident populations, which are augmented in winter by migrants. Farther south, Loggerhead Shrikes are present in east and south Mexico only during the winter months. Christmas Bird Count data suggest that the highest concentrations of wintering Loggerhead Shrikes are found in the Gulf Coast states of Texas, Louisiana, Mississippi and Alabama. Although the factors that trigger this species' migration are unknown, food availability is possibly involved since, in years when rodents are in great abundance, Loggerhead Shrikes sometimes spend the winter farther north than they do in other years. It seems that those breeding in areas experiencing more than ten days of snow cover in the year will migrate.

Migratory individuals of this North American species leave the breeding grounds during the period from about August to late October, some stragglers not departing until November. They migrate singly and by day, moving short distances and feeding en route, sometimes remaining in an area for a few days in order to feed. The nominate race travels up to 3360 km, from the northern Prairie Provinces southwards to Texas or Mexico. They return to the breeding grounds from mid-February to early May.

Adult, experienced shrikes migrate faster than inexperienced juveniles. They also spend shorter periods of time at staging areas. Data from ring recoveries of Great Grey Shrikes in North America and in central Europe suggest that this species is faithful to winter territories and migration stopover sites. Site-fidelity is considered an important strategy for surviving the non-breeding season.

Understanding of the winter distributions of migrant birds is important, because productivity and recruitment are influenced by conditions at several locations and periods in the life cycle of individuals. The Loggerhead Shrike is considered to be threatened in Canada, where its decline has been attributed to potential adverse factors on the wintering grounds. Researchers examined distribution patterns of stable-hydrogen isotope in the feathers of Loggerhead Shrikes, primarily of the western subspecies *excubitorides*, during winter at three places in northern and cen-

tral Mexico, in attempts to establish the relative abundance and origins of migrants; in addition, they investigated potential movements of Mexican winter residents. The results indicated that migrant Loggerhead Shrikes from northern breeding grounds accounted for 28.1% of individuals in north-central Mexico, 73.7% in north-eastern parts and 63.8% in south-central Mexico. The evidence further suggested that a few individuals from the south-western USA and north-eastern Mexico move into the Chihuahuan desert for the winter period.

Lesser Grey Shrikes and Red-backed Shrikes have much smaller ranges on the non-breeding grounds in the Kalahari basin, in southern Africa, than they do on the breeding grounds in Europe and western Asia. A study in Botswana investigated whether, as a result of competition, habitat segregation occurs on the non-breeding grounds. Surveys of these two shrikes were conducted by means of point-transect counts in 19 vegetation types, and it was found that clear differences in habitat distribution were apparent between the species and also, in the case of the Red-backed Shrike, between the sexes. Female Red-backed Shrikes occupied more densely wooded bushveld than males, and Lesser Grey Shrikes occupied the most open habitat and overlapped more frequently with male Red-backed Shrikes than they did with females of the latter. More subtle differences along gradients of herbaceous ground cover suggest that differences in habitat quality may be involved; the Lesser Grey Shrike, being the dominant species, tends to occupy the best habitat, while the most subordinate in rank, female Red-backed Shrikes, were forced into the poorest habitat. The difference between the sexes of the Red-backed Shrike in habitat occupation on the non-breeding grounds are believed to be the first documented example of such differences for any Palearctic-African migrant passerine.

The entire world population of the Lesser Grey Shrike vacates its Eurasian breeding grounds and moves into a non-breeding area, in the thornveld of southern Africa, that is ten times smaller than its breeding range. The species is abundant in open savanna habitat in its non-breeding quarters, chiefly in the Kalahari basin, where it is regularly spaced in individual territories and behaves conspicuously as a perch hunter. It has declined considerably during the last 200 years, and the non-breeding grounds offer highly favourable conditions for assessing and monitoring the world population (see Status and Conservation).

One of the most intensively studied members of the family is the Red-backed Shrike. In a long-term study of a population of this species in south-west Germany, the arrival time, the duration of stay and the time of departure were documented. The arrival phase extended over a period of 20–28 days, with an average of 24 days, and the average date of first arrival was 6th May. The pattern of arrival within the population, however, differed strikingly from year to year. In addition to the influence of the weather, there was an apparent correlation between arrival time and the time of departure in the preceding year. The average arrival of first-year individuals was correlated with the date of hatching and was later than that of older ones. The females reached the breeding grounds on average two days after the males, and laid the first egg 5–15 days after arrival. Among pairs for which the first breeding attempt was successful, the males stayed for an average of 75.5 days and the females for 69.7 days. Those having successfully reared a replacement brood remained for much longer time, males for up to 120 days and females up to 101 days. The duration of stay of unmated individuals was difficult to determine, as these were not faithful to any particular area; as the season advances, they attempt to make contact with breeding pairs and sometimes become involved in the care of the young, even taking over the role of parents (see Breeding). In such cases, their departure from the breeding grounds was delayed until the end of the postnuptial moult. The majority of the adult Red-backed Shrikes left between 20th July and 10th August, the date of departure being determined by the frequency of replacement broods. During a total of 13 years, the latest departures were four times in September and twice in October.

West European breeding populations of the Red-backed Shrike spend the non-breeding season in southern and eastern parts of Africa. Having initially headed east or south-east, they have to change their migratory direction to that of south in order to cross the eastern Mediterranean Sea. A team of researchers radio-tracked six Red-backed Shrikes which departed from the Greek island of Karpathos. The shrikes left the island after sunset, between 19:58 and 21:30 hours MET. Their mean flight direction was 132°, which indicates a south-easterly heading, and suggests that at Karpathos the Red-backed Shrikes had not yet changed their migratory direction. On the basis of the wind speed, wind direction, departure time and flight velocity, it was calcu-

A female **Woodchat Shrike** surveys her nest which is tucked into the shady foliage of a Spanish olive tree. It overflows with a brood of five well-grown nestlings clamouring for food. Once hatched, these hungry nestlings are fed by both parents for 15–18 days, and once fledged they will continue to be provisioned by their parents for up to six weeks. A study of this species in central Europe suggests that breeding success is fairly low: of 553 eggs in 112 nests, only 68.9% hatched, and only 42% produced fledged young.

lated that the shrikes would have to fly for ten hours before they reach the Nile Delta at the coast of Egypt.

Migratory populations of two sympatric species, the Bull-headed and Brown Shrikes, were studied in northern Japan between 1992 and 1997. Although 18% of ringed Bull-headed Shrike males returned to the breeding area used in the previous year, no females did so. In the case of Brown Shrikes, however, 43% of ringed males and 13% of ringed females returned to the area. Even Bull-headed Shrikes which had bred successfully did not always return to the same nesting area in the following year, whereas successful Brown Shrikes remained faithful to their past breeding site. Curiously, Brown Shrikes decreased by 67% as a result of habitat loss over four years, whereas the Bull-headed Shrike population was stable. The differences in degree of philopatry were inconsistent with the population trends of the two shrikes. It may be significant, however, that Bull-headed Shrikes exhibited no particular habitat preferences in the study area, whereas Brown Shrikes bred mainly in natural grassland with shrubs. Since available habitat for Brown Shrikes has decreased rapidly in and near the study area, the philopatry demonstrated by this species could result from a scarcity of habitat, which would inhibit dispersal. In contrast, Bull-headed Shrikes, because they are habitat generalists, may have a higher tendency to disperse.

Male Red-backed Shrikes in Germany and Italy demonstrated a high degree of fidelity to the territories which they had established in previous years, and this was found to be true especially of older individuals with several seasons of successful breeding experience. Such site-fidelity is considerably less marked in sub-optimal habitats. Adult and juvenile females, on the other hand, were significantly less faithful to their former territories, and this was the case irrespective of the age and prior experience of the individual. Similarly, male Southern Grey Shrikes in the Negev Desert, in Israel, are resident throughout the year, but females remain only for the breeding season; indeed, no females return to the same territory in subsequent seasons. As a consequence, the males, which are well acquainted with their territory, and with proven breeding success from previous seasons, begin the nest-building process for all breeding attempts and, when pairing occurs, the male leads the female to the nest-site, which is built in the same place every year. Evidence of the male's fidelity to the nest-site was provided by the presence of nests from previous

breeding seasons in bushes and trees with active nests. One saltbush (*Atriplex*) contained 19 nests, suggesting that shrikes in that territory had returned to breed in the same bush for at least nine consecutive breeding seasons.

Male Loggerhead Shrikes may display higher site-fidelity on breeding grounds than females. In south-eastern Alberta, however, there was little difference between the sexes in the numbers that returned to within 4 km of the previous year's territory. Of 48 males and 48 females, all ringed, 18 males and 13 females returned to the site where they had nested in the preceding year.

Relationship with Man

The principal genus of Laniidae is *Lanius*, a name which is Latin for "butcher". Connected with this is the word *laniare*, meaning "to tear" or "to shred", actions associated with a butcher. The scientific name of the shrike is, of course, an allusion to the laniid practice of impaling prey on sharp objects such as thorns, and the habit of subsequently tearing prey to pieces.

The vernacular name of "shrike" is related to the word "shriek", and is the modern form of the Old English *scric*; it is allied to the Icelandic *skrikja* and the Late German *schrik*, among others. Such words surely refer to the vocalizations of laniids, which are generally harsh and, to the ears of many, unpleasant sounds; one might say that they are "shrieking" calls. Perhaps more intuitively, the modern German language refers to shrikes as *Würger*, which means "stranglers". The Great Grey Shrike is the *Raubwürger*, *rauben* meaning "to plunder" or "to take by force", so that its full name conjures up the picture of a somewhat ferocious bird. No less sinister is the Red-backed Shrike, one of the German names of which, *Neuntöter*, means literally "killer of nine". Legend has it that this shrike would "murder" nine creatures before it took a break.

The oldest reference to the shrike appears to be in the Sanskrit literature from ancient Indian cultures. Many of these can be traced back to 2500 BC. Many Indian languages have evolved from the parent Sanskrit, and in one of these, Marathi, the regional language of the Maharashtra state, a few peculiarly descriptive names for shrikes are mentioned, such as *Khatik*, meaning "the butcher", or *Naklya Khatik*, "the butcher who mimics". Another name, *Gandhari*, has a special reference to one of the popular ancient Indian epics, namely the "Mahabharata", the longest poem in any language, and *Gandhari* is the name of the blindfolded Kaurava Queen, who chose to wear a mask over her eyes so that she could experience the same life as her blind husband Dhrutarashtra. In the Marathi language, the Southern Grey Shrike is called *Gandhari*.

The shrike is also mentioned in the epic mythology of Mahabharata, dating from 400 BC to AD 400, where it is referred to as *Latvaka*. It is interesting to note that the Sanskrit name for a staff, with a bulbous club at the top, is *Khatvanga*. *Latva*, which is another Sanskrit name for the shrike, could originate from *Khatvanga*, because the typical shrike, like the staff, has a relatively large head for its size. This, of course, is reflected also in the name "Loggerhead" in North America. The Sanskrit name for the butcher is *Khattika*, probably an original form of the Marathi name *Khatik* for the "butcher bird", alluding to its habit of impaling.

Some shrikes are well-known vocal mimics. The Long-tailed Shrike, the Bay-backed Shrike (*Lanius vittatus*) and the Southern Grey Shrike, which are commonly found in Maharashtra, all mimic the calls of other birds. The two Sanskrit names for the shrike, *Latva* and *Latushaka*, are possibly derived from the root verb *lat*, meaning "to cry", and *vak*, "to speak". Another suggestion regarding the derivation of *Latushaka* is that it comes from the same verb *lat* but combined with the word *ushas*, the latter meaning "morning and evening light": thus, the bird which calls and hunts from daybreak until late evening is the *Latushaka*, or the shrike.

There are numerous references to the shrike in the system of medicine known as "Ayurveda". This ancient practice was widespread in the Indian Subcontinent, where the shrike was supposed to have special medicinal properties. Two second-century Sanskrit texts refer to the shrike as *Lattushaka*, and it is noteworthy

An adult **Southern White-crowned Shrike** brings food to a brood of three nestlings. This species and its congener, as well as Souza's Shrike (*Lanius souzae*), are the only shrikes known to build atypical nests. They plaster the basic structure with cobweb, producing a moulded or sculpted cup with a relatively smooth silvery-grey finish. These smoother, smaller, more camouflaged nests recall those of helmet-shrikes (Prionops).

[*Eurocephalus anguitemens anguitemens*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

The female **Red-backed Shrike** usually lays a clutch containing 3–7 eggs. Clutch size tends to decline from eastern to western Europe, and from early to late in the season. After they hatch out, the nestlings continue to be brooded by the female for the first week, while the male continues to bring food to the nest. Thereafter, the brood is fed by both parents, as seen in this image. The nestling period normally lasts 14–16 days, but it sometimes extends to 18–20 days in bad weather.

[*Lanius collurio collurio*, Huidobro, Burgos, Spain. Photo: Joseba del Villar]

that the ancient Indians placed shrikes in a class “Pratuda”, consisting of pecking birds. These are described as birds that hit, beat or pierce the prey with the beak before consuming them.

Shrikes are mentioned also in a medieval Sanskrit text, *Vasantarajashakunam*, which is devoted to augury, the practice of interpreting omens from bird and animal behaviour. In this text the shrike is called *Ladva*, and it is believed that, if a person sees or hears a shrike in front of him or her, that person’s wish will be granted.

Elsewhere, the earliest documentation of shrikes and their relationship with man appears in art from the XII Egyptian dynasty, 1991–1786 BC. Shrikes are mentioned in almost all ancient natural-history books. They are included also in the *Sherborne Missal*, a lavishly decorated English medieval service book from the early fifteenth century. This magnificent missal incorporates a series of 48 depictions of birds, among them the shrike, which is identified by the Middle English name of “waryghanger”. The species in question appears to be a cross between the Great Grey Shrike and the Southern Grey Shrike, neither of which breeds in Britain, although the former is a winter visitor to that island.

True shrikes are miniature birds of prey. Indeed, the fact that they are able to capture and feed on relatively large animals has resulted in the bigger species of shrike being used in falconry. Unfortunately, however, their raptor-like appearance and behaviour had the effect that, until as recently as the middle of the twentieth century, both in Europe and in North America, they were generally regarded as harmful. This negative reputation was reflected not only in the writings of hunters and gamekeepers, but also, perhaps somewhat surprisingly, in those of some ornithologists. Even today, shrikes are still hunted by humans in many parts of the world, and they are particularly vulnerable when on migration. Many are killed in the Far East, the Middle East and several Mediterranean countries. In Georgia and Turkey, numerous Red-backed Shrikes are caught, blindfolded, and used as decoys to attract Eurasian Sparrowhawks (*Accipiter nisus*); the hawks are then captured, trained and employed in catching Common Quails (*Coturnix coturnix*).

In east Asia, large numbers of Brown Shrikes migrate through Taiwan in September, and many were frequently caught with il-

legal bamboo traps. This species was considered by local inhabitants to be a delicacy, and even in the late twentieth century it was by no means uncommon to see Brown Shrike kebabs being offered for sale at roadsides in rural areas. Remarkably, these shrikes were even barbecued and sold as food to tourists in Kenting National Park, in south Taiwan. Fortunately, conservation laws passed in 1989, and strengthened in 1994, have made these practices much rarer in occurrence, although they do still take place on a smaller scale. Taiwan is, of course, on a major flightpath used each year by massive numbers of migrating birds. In attempts to increase public awareness of the risks faced by these migrants, and especially the plight of certain species, conservationists persuaded the government to issue postage stamps and coins depicting some of them, the Brown Shrike being one such species. Furthermore, one leading scientist, in an effort to stop people from eating the shrike, collected photographs illustrating that the dissected birds were full of parasitic worms; he then had the pictures reproduced on posters, which he set up in the areas where the capturing of Brown Shrikes was most commonly practised.

Birds are still considered a “legitimate” source of food for humans in many parts of the world, particularly in Asia, Africa and South America. It is very likely that shrikes are consumed by people in China, the Philippines and elsewhere, but there is little information on the numbers of shrikes involved.

During the course of excavations of sites of native Pueblo peoples in north-eastern Arizona and southern Utah, a considerable number of bird bones were found. These were associated with archaeological material dated between AD 700 and 1300, and among several avian species were the bones of Loggerhead Shrikes. Whether the natives exploited the shrikes for food or used them for other purposes is not known.

Status and Conservation

Only one member of the Laniidae is currently considered to be globally threatened. This is Newton’s Fiscal, the conservation status of which is listed as Critical. One other species, the Mountain Shrike, is regarded as Near-threatened.

Co-operative breeding has been confirmed in a few group-territorial Afrotropical shrikes, including the **Magpie Shrike**. This image shows the dominant female at the nest, accompanied by two other adults, presumably the dominant male and a helper. It is thought that breeding pairs are always monogamous even though they may be accompanied by up to nine helpers. These subordinate individuals are probably related to the dominant pair, and most likely offspring from earlier broods on the same territory. This kind of delayed dispersal is poorly understood, but usually related to density-dependent processes, such as competition for space and territories.

[*Corvinella melanoleuca melanoleuca*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

Newton's Fiscal, confined to the island of São Tomé, in the Gulf of Guinea, is rare. It was first discovered in 1888, and four decades later, in 1928, 13 specimens were collected from the island. The species was not seen again for more than 60 years and was assumed to have become extinct. In 1990, however, an expedition from Britain encountered a single individual in the south-west part of São Tomé, near the source of the Xufexufe River. Since the mid-1990s, this shrike has been seen with some regularity, mostly in the Xufexufe catchment, but its total population is thought to be very small, numbering probably fewer than 50 individuals. The reasons for its obvious rarity are not known, but it may be relevant that Newton's Fiscal, unlike others of its genus, inhabits forest, much of which on the island has been damaged or destroyed, both in the lowlands and at middle elevations. Most of the cleared areas were used for growing cocoa and coffee, which were valuable exports during the Portuguese administration of the island. In more recent years, however, land privatization has resulted in a huge increase in the number of small farms, with consequent removal of large numbers of trees. Most observations of this species have been made in undisturbed forest below 700 m or so. Introduced predators, such as the black rat (*Rattus rattus*) and the mona monkey (*Cercopithecus mona*), may be having an adverse impact on the shrike's population, but this needs to be verified.

The Near-threatened Mountain Shrike is found only in the Philippines. Although its precise range is small, its habitat is apparently secure, and the species is present throughout this habitat. It is probably not at immediate risk, but further information is needed. The Mountain Shrike has generally been considered uncommon throughout its small range, but it now appears that it is fairly common in upland areas that are not under human pressure. Nevertheless, population surveys are required, as also is research into its basic biology.

Although no other laniids are "officially" at risk, many of them have suffered worrying declines in recent decades. Before examining such phenomena, however, it should be borne in mind that population estimates need to be treated with caution, primarily because of the problems involved in the detection of shrikes, even at relatively short distances. Various studies have revealed that it is difficult to achieve accurate estimates of the numbers of breeding pairs of *Lanius* species. During research on shrike biol-

ogy in western Poland, the numbers of breeding pairs were calculated from special counts made in the pre-breeding period, combined with intensive searches for nests, and colour-ringing. In the matter of estimates of Red-backed Shrike and Great Grey Shrike population sizes, it was demonstrated by means of empirical tests that point counts and line-transect methods led to serious underestimates of the true numbers. Moreover, an "improved mapping technique" underestimated the true numbers of Red-backed Shrike breeding territories by as much as 45–80% and underestimated those of the Great Grey Shrike by just under 40%. It was found, however, that accurate numbers of breeding pairs of Great Grey Shrikes could be obtained by making counts during the pair-formation period, while intensive nest searches were the most effective method of determining Red-backed Shrike numbers.

Notwithstanding the problems of assessing the numbers of shrikes in a population, it is clear that many species have undergone reductions in their numbers since the second half of the twentieth century. In central Japan, for example, a long-term study of the Brown Shrike on the Nobeyama Plateau has documented a massive decline in this species' breeding population, and similar declines are evident elsewhere in Japan, including Hokkaido. The reasons for this are uncertain, but habitat alteration and loss in the breeding areas have been suggested, while some consider that fires on the wintering grounds in Indonesia may be contributory factors.

In Europe, an interesting project for rehabilitating a population of Red-backed Shrikes was undertaken at the Bargerveen peat bogs, a nature reserve in the Netherlands. Following a drastic decline in the numbers of this species breeding there during the past century, a team of conservationists improved the shrikes' food supply by a programme of re-wetting of the peat bogs. This led to a dramatic increase in the number of breeding pairs, from a few singles in the 1970s to more than 100 pairs in the 1990s. The team demonstrated also that a reduced diversity of invertebrates had caused the demise of the Red-backed Shrike in the Dutch dunes. If these restoration projects are to be successful in the long term, it is important to discover the causes of the decrease in the invertebrate diversity.

The Red-backed Shrike breeds mainly in human-altered agricultural areas, and it has declined significantly in western Eu-

rope since the late 1960s. In order to develop effective conservation strategies, it is necessary to gain detailed information on the constituent ecological and environmental elements that make up the species' breeding habitat in this landscape. Species-distribution models are being used increasingly to provide such information. Most studies investigate the environmental pattern of a species' distribution, assuming that records are reliable indicators of habitat suitability, but some individuals and pairs may be located outside the environmental bounds of their species' breeding niche and these could reduce the accuracy of the model and limit its utility. Parameters related to the breeding success of the Red-backed Shrike in southern Belgium were integrated into a fine-scale presence-only modelling framework to demonstrate this problem and to ascertain the critical habitat requirements of this species in relation to conservation management. It was found that, above a certain environmental threshold, individuals occurred but did not breed successfully, which indicated that the species' breeding niche is ecologically narrower than would be suggested by standard distribution modelling. Many elements, such as nest-site availability, food density and availability, and shelter from predators, were important in the breeding habitat of the Red-backed Shrike.

The entire world population of the Lesser Grey Shrike migrates to southern Africa from its breeding grounds in south and east Europe and western Asia. Its non-breeding range in the African thornveld is much smaller than its breeding range. This species has declined considerably during the last 150–200 years, and the non-breeding grounds, where the shrike is abundant in open savanna and is regularly spaced in individual territories, offer favourable conditions for assessing the world population. During the mid-1990s, this was estimated at 5,000,000–7,300,000 individuals. A huge decrease has been reported in the west of the breeding range, where the Lesser Grey Shrike is now extinct in many countries of western and central Europe. Only isolated populations, containing up to 30–50 pairs, remain in Spain and France. This contraction of range towards the south-east, combined with a decline in numbers in most European countries, is evidently part of a longer-term trend that has been apparent since the middle of the nineteenth century, and especially during 1970–1990, affecting up to a third of the European population.

Long-term changes in climate and farming practices have been identified as possibly the main reasons for the decline of the Lesser Grey Shrike. Spanish researchers studied several peripheral populations of this species in southern France and north-east Spain, at the western limit of the breeding range, in an attempt to ascertain the effects of environmental change. They also looked for evidence of climatic changes in the breeding and wintering areas of this shrike and related effects on vegetation. They found that fluctuations from one year to another were closely similar in all of the studied populations, suggesting that the declines were probably influenced by a common factor. In one peripheral population, there was clear evidence of climatic change, in the form of increased thermal oscillation, that could have resulted in a decrease in the vegetation index in the area. It was thought likely that climatic variables in the breeding area could account for fluctuations in abundance of some populations, and it was evident that environmental conditions experienced by some populations could influence the fate of the neighbouring populations, too. The results indicated that the studied populations were spatially synchronized, so that conservation efforts should be applied at a wide scale, encompassing all of the isolated populations at the western border of the Lesser Grey Shrike's range in the Mediterranean area.

Whereas most of the world's threatened bird species face the problem of deforestation, this is not the case with the *Lanius* shrikes. On the contrary, these species live in semi-open habitats and have benefited from forest clearance, having adapted quickly to low-intensity farming. More recently, however, the era of intensive farming and the industrialization of agriculture, which began in the second half of the twentieth century in Europe and North America, shrikes have suffered major setbacks. Large-scale increases in field size have led to the loss of commercially non-productive habitats, such as hedgerows, bushes and isolated trees, ponds, banks and ditches and grassy edges and tracks, which are favoured by shrikes. Coupled with this habitat loss has been the widespread use of pesticides, which have reduced the shrikes' food resources.

Since the 1950s, the Loggerhead Shrike has suffered a serious decline in North America. It is listed as "endangered" in Canada, and as "endangered" or "threatened" in 14 US states.

Parental care in shrikes involves interesting anti-predator behaviour. This was discovered during a field study of the **Southern Grey Shrike** which involved colour-banding nestlings at the age of 10–13 days.

Although the nestlings were too young to fly away, researchers were surprised to find that these broods disappeared almost immediately after banding. It transpired that females of this species responded to extreme disturbance by prodding each nestling in turn until it dropped to the ground, and then coaxing it to an alternative hiding place. In all cases, the entire brood was found together in a cavity excavated in the ground and concealed by dense vegetation, 3–55 m from the original nest.

According to breeding-bird surveys, this species suffered a mean annual decrease in population size during 1968–2003 of 9.4% in Canada and 3.8% in the USA. In Canada, the small isolated breeding population in south-east Ontario had been reduced to just 18 pairs in 1997, and conservationists decided to establish a captive population in order to preserve the population's genetic diversity and possibly as a means of re-establishing populations elsewhere. A total of 43 nestlings was collected and captive-breeding began in 1998. In 2001, Wildlife Preservation Canada undertook experimental "field breeding" and subsequent release of shrikes. Special cages were constructed from panels that could be bolted together on site, in this case a pasture around a hawthorn within natural shrike habitat. These breeding cages comprised two or three units which had a common wall or were joined by a corridor. The male and female shrikes were initially placed in separate units, and provided with plenty of insect food and nesting material. As soon as courtship behaviour commenced, the door separating the units was opened, allowing breeding to take place. The parents reared the young, which learned how to kill and impale live prey, including not only that provided but also frogs, snakes and others that entered the cages and were quickly caught; the young learned also to recognize the parents' hawk-alarm call, which prompted them to hide in the hawthorn. At the time when the juveniles would normally leave the parents, they were moved into a release cage with one or two sets of young from other broods. They remained for 7–10 days in this cage, and were released when they were seen to hunt and impale their own prey. The parents were then removed to the "wintering facilities" until the following spring. Supplementary feeding areas were set up, with crickets and mealworms provided, until the released juvenile shrikes either stopped feeding from these or left the area.

The project started with three pairs in 2001 and six in 2002, and very soon there were two field breeding-and-release sites, one with 14 sets of breeding cages and the other with 12 sets. Between 2001 and 2005 a total of 110 young was released into the wild, and in 2006 111 young were released and 17 others retained in order to augment the captive population. From 2005 onwards, captive-bred shrikes have paired with wild individuals and bred successfully, indicating that they are able to migrate southwards, survive the winter and return in the following spring to breed.

Farther south, in south-west USA, the Loggerhead Shrike of the subspecies *mearnsi* has been saved from near-extinction by

the efforts of the San Clemente Loggerhead Shrike Rescue Team, housed at the San Diego Zoo. The population of this taxon, which is confined to the island of San Clemente, off southern California, had fallen to a critically low level, with just four breeding pairs and ten hatchlings in 1998, and urgent action was required in order to save it. The team, having successfully eradicated introduced predators on the island, instigated a captive-breeding programme and released artificially incubated and hand-reared Loggerhead Shrikes. In 2006, there were more than 40 pairs breeding on the island and these produced 160 young. It is estimated that more than 80% of the island's current Loggerhead Shrike population consists of released captive-bred individuals and their descendants.

Protective fencing resulted in a higher abundance and a greater species richness of birds, including the Loggerhead Shrike, which was found also to nest more frequently inside the fenced area than outside it. This increase in abundance may be related to an increase in abundance of seed and invertebrate food resources and, particularly for the shrike, an increase in reptile species. Sites used by Loggerhead Shrikes in the USA did not differ in accordance with disturbance, such as that caused by military training, with harvesting of hay or with the number of years since burning took place. Moreover, the shrikes dispersed along connecting corridors of vegetation, rather than directly between equally sized isolated patches of habitat. Management for resident shrikes should, therefore, include a patchwork of grassy habitats and sparsely vegetated bare areas at the scale of individual shrike territories. Similarly, comparisons of occupied and unoccupied sites in southern Alberta, in Canada, indicate that the amount of suitable breeding habitat could be increased by management practices that increase the area of grassland. A very important nesting habitat for Loggerhead Shrikes is scrubland, the loss of which has been accompanied by a corresponding reduction in both the range and the numbers of shrikes.

Invading species appear to have a negative impact on shrike populations in North America, as evidenced by the reaction of shrikes to the red imported fire ant (*Solenopsis invicta*), which is an aggressive, non-indigenous species that is a threat to native biota in the south-eastern USA. One study in Texas investigated whether the ants reduced the insect prey available to the shrikes, and it was found that both insect biomass and shrike abundance were negatively correlated with the level of *Solenopsis* infestation. The data suggested also that the shrikes avoided wintering in areas invaded by the ants and that this avoidance might result from reduced insect availability in such areas.

In some studies, the reproductive success of Loggerhead Shrikes has been relatively high, something that would seem incompatible with the recent decline in the species' numbers. Although much good habitat has been lost, there is still sufficient suitable but unoccupied habitat to accommodate a larger population. Management initiatives for this shrike should be directed towards increasing the amount of medium-height and perhaps tall grass in areas that are favourable for the species, and one way of achieving this is to control the grazing and mowing of grasslands. In addition, hedges, brush along fence lines, and scattered trees in pastureland and fields should be retained as potential nest-sites, and also as hunting perches. The Loggerhead Shrike's continuing decline may be due, at least partially, to its withdrawal from parts of the range where human activities have reduced the density of perches.

Several key management priorities have been identified for the conservation of the Loggerhead Shrike. Among them are the determining of migration stopover sites and wintering areas and the species' susceptibility to human disturbance at these locations; assessment of its dietary needs and the influences of weather, season, land use and biocides on food availability; determining of the mortality rates of juveniles and adults throughout the annual cycle in different habitats; and research into the degree of niche overlap between the Loggerhead Shrike and potential competitors in order to determine whether the shrike's productivity is correlated with the presence or absence of these species. D. A. Keinath and C. Schneider, in 2005, summarized the several decades of work carried out on the Loggerhead Shrike in North America, and their recommendations for the conserva-

Once fledged, young shrikes remain in or near the nest tree or bush for a few days. During this phase they are vulnerable to predation and therefore tend to remain in dense cover, although this **Grey-backed Shrike** is already a little more adventurous. After about one week it will fly increasing distances, usually prompted by its attempts to follow the adults around the territory. Overall, it will remain more or less dependent on them for 3–4 weeks after fledging, after which it will be able to subsist by foraging independently. A few weeks later it will leave the territory entirely.

There are no globally threatened shrikes, but **Souza's Shrike** is one of the least common. It is sparsely distributed and local in a fairly large range from Rwanda and Tanzania to Namibia and Zimbabwe. It is associated with light woodland and the forest-savanna ecotone, habitats which in Africa have suffered from overgrazing, burning and the intensification of agriculture. There is a shortage of information about changes in distribution or abundance, and while this species is not likely to be immediately threatened its status requires monitoring.

tion of the species effectively apply to all of the laniid shrike species throughout the range of the family.

Whereas localized declines can often be attributed to proximate causes, the synchronous range-wide decline in shrike populations is difficult to explain. It can probably be attributed in part to loss of open habitat and, to some extent, reforestation in some northern regions, but there are places where a good deal of suitable habitat remains currently unoccupied by shrikes, and declines have occurred even in regions with much open habitat. Furthermore, in some non-breeding quarters where the habitat has not changed, the numbers of shrikes have fallen. A variety of factors, mostly anthropogenic but also natural, would seem to be involved in these declines.

Anthropogenic impacts fall into the main categories of direct mortality and habitat reduction. A combination of pesticide effects and habitat loss seems likely to lead to declines. Both breeding and wintering habitats have been shrinking in most areas where shrikes are found, primarily because of intensive agricultural practices that have resulted in the removal of shrubs and shelter-belts. Although pesticides can lead to the thinning of eggshells or have adverse effects on the behavioural development and hunting ability of young shrikes, it is more likely that their most serious impact is indirect, in that they cause a long-term reduction of insects. Another problem is that shrikes often nest at roadsides, at least in some parts of their ranges, and, because they fly low to the ground, they are frequently hit by vehicles; fledglings and juveniles, being inexperienced, are especially vulnerable. This is likely to become an increasing risk as more shrikes are forced to use roadside breeding habitats, and as road traffic has increased greatly and continues to grow in volume throughout the world.

Invasive species have been particularly problematic for island populations, such as that of the Loggerhead Shrike on San Clemente Island. Habitat loss on islands is caused partially by overgrazing by introduced feral livestock, especially domestic goats. Moreover, feral domestic cats are responsible for high rates of nest loss and the deaths of incubating adults, and the replacement of native vegetation with introduced annual grasses and exotic plants decreases the quality of foraging habitat. Overgrazing and crop monoculture reduce insect abundance and diversity, and exotic grass species growing in solid masses make for harder hunting than is the case with native varieties, which

grow in bunches and allow the shrike to see its prey. In the southwest USA, invasive plants such as cheatgrass (*Bromus tectorum*), introduced from Europe, cause native bushes to grow in small stands, surrounded by the exotic. It was found that Loggerhead Shrikes in this situation might be forced by the habitat limitations to breed closer together than normal.

Some of the range contractions and population declines suffered by shrikes may result from natural successional change in habitats, such as reforestation, but the importance of this compared with anthropogenic changes is unclear. Other natural events, primarily predation and random weather events, have been shown to cause nesting failure and local reductions in numbers, but these factors are not thought to be responsible for more widespread declines, although they can add to the existing pressures on populations. For example, reduced nest success is associated with roadside and fence-line habitats, where predators are more common. Further, the spread of some major nest predators, including feral cats and corvids, has been facilitated by patterns of human settlement.

The following recommendations, here summarized, were compiled by the Canadian Wildlife Service for the conservation of Loggerhead Shrikes, but they could equally well be regarded as a guide for ensuring the future of laniids in similar habitats in Europe, Asia and Africa. Native grassland in breeding and wintering areas should be preserved; where this is not possible, seeded pastures should be provided. Agricultural policies that encourage the conversion of native grassland to cropland should be altered. Scrub habitat in the shrike's breeding range should be preserved. Suitable habitat should be protected through incentive programmes, donations, land trusts, leases and purchases, or through designation of suitable habitat as natural areas. Provision of areas of adequate size for breeding shrikes is required, taking into consideration the fact that females sometimes mate with more than one male or switch mates. Areas should be large enough to support several average-sized territories (about 2.7–25 ha/territory) of asymmetrical shape. Low, thick shrubs and trees should be maintained along fence lines, in abandoned farmyards and throughout otherwise open pastures and fields. Shelter-belts should be diversified by incorporating thorny trees and bushes, and a strip of grass 2–4 m wide should be planted around them to increase foraging areas near nest-sites. In areas with taller vegetation, grazing should be implemented where pastures provide suitably short

vegetation for shrikes to forage; pastures are often the preferred habitat of certain species. A few areas of tall grass should be maintained within pastures, as they encourage small mammals, which are potential shrike prey, and in areas with naturally short vegetation areas of taller grass, taller than 20 cm, can be increased by control of grazing and mowing; although shrikes prefer to forage in short grass, success may be higher in areas of tall grass, where vertebrate prey are more abundant. The use of biocides should be reduced whenever possible in order to protect insects and other prey species exploited by shrikes. A number of additional recommendations with regard to habitat management were given.

In order to understand the decline of shrikes, as well as that of other wildlife living in agricultural habitats, it is necessary to include parasitic species in ecological and environmental studies, at the same time gathering information on the general condition and health of individuals. As big changes are likely to occur on a large scale in agro-ecosystems in Europe, this information could prove to be useful, at least in the short term. Polish researchers extracted chewing lice (Mallophaga) of the species *Docophorulus coarctatus* from 36 museum specimens of the Great Grey Shrike. They gathered samples of five female and five male lice from each bird. Female lice were bigger than the males, although the size of both sexes of lice was positively correlated with the size of the individual shrike, and also with the density of lice on the individual host. In a similar study in Slovakia, during 1962–1974, the louse parasite community on Great Grey Shrikes was studied. This consisted of three species, *Docophorulus coarctatus*, *Brueelia cruciata* and *Lanicanthus camelinus*, all characteristic of this shrike; lice were present on 104 of the 108 specimens examined. Sex ratios of lice were biased towards females and were not correlated with the subpopulation size of lice on individual hosts. While the risk that parasites and pathogens pose to endangered species is evident, this factor is normally overlooked by scientists when considering the causes of decline of species.

In a study of adult and nestling Lesser Grey Shrikes from a stable population in central Europe, three species of haemoparasite (of the genera *Haemoproteus* and *Trypanosoma*) and two ectoparasite taxa, namely *Menacanthus camelinus* and feather mites (Acarina), were found. Although this particular shrike population, breeding in an area with traditional and extensive farming, seemed not to be under any heavy parasite pressure, indirect measures of immunocompetence revealed an association between haemoparasites and a reduced health status. The effects on the

shrikes of other parasites, such as helminths, need also to be assessed. *Haemoproteus lanii* was found to be the most common blood parasite in Red-backed Shrikes in the southern Czech Republic. Female shrikes infected by this parasite started egg-laying later in the season than uninfected females, and this could ultimately have an impact on the reproductive output of the shrike. Infected males had significantly longer wings and a larger black tail than uninfected individuals. Moreover, mating was assortative with regard to infection status.

We still know relatively little about which factors contribute to mortality during the various life stages of shrikes, and no systematic study has been made of the lifespan and adult survivorship largely because of the difficulties posed by undetermined levels of dispersal between breeding seasons. It is important, therefore, to ascertain the mortality rates of juveniles and adults throughout the annual cycle in different habitats, and at the same time to throw light on those factors contributing to mortality and to causes of decline. In addition, there are very few data on disease and body parasites, which may have an important role in the widespread decline of shrikes.

Shrikes can be bred with relative ease in captivity, as has been found to be the case with Loggerhead, Great Grey, Long-tailed, Woodchat and Red-backed Shrikes. Captive-breeding programmes, followed by the releasing of the young into their natural environment, can help to maintain shrike populations in the best possible way. Of course, an understanding of their habitat requirements and behavioural traits is essential before such releases of captive-bred individuals are made.

Although shrikes have in the past sometimes had a bad reputation among humans (see Relationship with Man), this is undeserved and, in the modern world, they are generally regarded in a better light. While shrikes have gained a better reputation, however, they are confronted with drastic habitat changes in many parts of the world. The decline of *Lanius* shrikes, combined with their attractive appearance and the fact that they are generally conspicuous and easy to study, prompted the creation of an International Shrike Working Group. This group of enthusiasts, which met for the first time in Florida, USA, in 1991, organizes regular meetings, which are followed by the publication of proceedings. So far, it has taken a strong interest only in the laniid shrikes, but the other shrike-like birds, such as the malaconotid bush-shrikes, should not be forgotten. Very little is known about them, but it is obvious that a few species are already endangered.

Emin's Shrike is generally uncommon and localized in shrubby savanna and forest clearings. It is distributed discontinuously from Mali and Ivory Coast in the west to Sudan, DR Congo and Uganda in the east. This range is fairly extensive, roughly 130,000 km² in occupied area, while the global population is estimated at fewer than 70,000 individuals. Although these figures surpass the thresholds for threatened status, they are based on sparse information and suggest that the species may need conservation attention.

[*Lanius gubernator*, Laminga, Jos Plateau, Plateau State, NC Nigeria. Photo: A. P. Leventis]

The **Mountain Shrike** is a restricted-range species present in some important Philippine Endemic Bird Areas: the Mindoro EBA, the Luzon EBA, and the Mindanao and Eastern Visayas EBA. It is generally uncommon, but healthy populations appear to persist in upland and mountain-top habitat that remains free from anthropogenic habitat loss. Thus, although the species is generally uncommon in a small range it is not thought to be in immediate threat of extinction. It is currently considered *Near-threatened*.

Genus *LANIUS* Linnaeus, 1758

1. Tiger Shrike

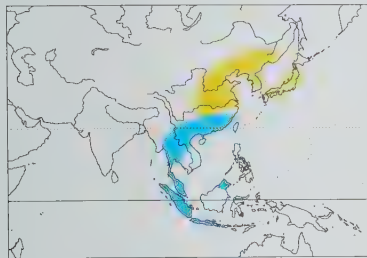

Lanius tigrinus

French: Pie-grèche tigrine **German:** Tigerwürger **Spanish:** Alcaudón Tigre
Other common names: Thick-billed Shrike

Taxonomy. *Lanius tigrinus* Drapiez, 1828, Java.

Appears closely related to the superspecies formed by *L. collurio*, *L. isabellinus* and *L. cristatus*; possibly closest to last of those, which has similar mating system and with which hybridization recorded in Russia and Japan. Monotypic.

Distribution. Breeds extreme SE Russia (Ussuriland), NE & E China (E from Shaanxi, Sichuan and Guizhou), Korea (except S coast) and Japan (Honshu, Sado, E Kyushu); non-breeding E Myanmar and SE China S to Peninsular Malaysia, Singapore, N Laos, C Vietnam and Greater Sunda (including N Borneo).

Descriptive notes. 17–18.5 cm; male 27–29 g, female 29–37 g. A relatively small shrike with rather short, graduated tail, strong and heavy bill with hooked tip. Adult male has light grey crown to upper mantle, black frontal band, lores and ear-coverts forming facial mask; lower mantle to rump and uppertail-coverts deep rufous-brown with coarse blackish bars; upperwing brown with pale or reddish fringes; tail warm brownish-rufous, outer feathers paler; throat, cheek and underparts white, flanks sometimes faintly dark-barred; iris dark brown; bill blue-black, tip black; legs greyish-black. Female is similar to male but variably duller, usually with

much white on lores, sometimes faint paler supercilium, less blackish face mask, duller grey crown and nape, duller brown upperparts more prominently barred, underparts with buff-tinged flanks and side of breast, blackish bars on flanks and belly. Juvenile is like a very dull female but with face mask faint, obvious pale supercilium, has crown to side of head and upper mantle dark reddish-brown or greyish-brown with contrasting narrow dark bars, rest of upperparts reddish-brown and heavily barred, becoming brighter rufous on lower back, rump and uppertail-coverts, dirty white below, chin whiter, breast and flanks with buff wash and heavily dark vermiculations. Voice. Song described as a resonant and musical warble, but subdued at beginning of courtship. Call a loud, sharp “chick” or repeated “tsik-tsik-tsik-tsik...”; territorial call “tcha-tcha-tcha...” or “gichi-gichi...”; alarm a loud, scolding chatter, like that of *L. cristatus* and *L. bucephalus* but louder and harsher.

Habitat. Breeds in temperate, deciduous and mixed lowland and hill forests with thick undercover and small open areas, also forest edges, thickets, wooded cultivated areas, orchards and, rarely, suburban parks; in SE Russia found along rivers and on gentle slopes with deciduous woods of elm (*Ulmus propinqua*, *Ulmus japonica*), Japanese alder (*Alnus japonica*) and Mongolian oak (*Quercus mongolica*). In non-breeding season found in edges and clearings of primary and secondary evergreen and broadleaf lowland forests; also cultivated areas, mangroves and gardens. Usually from sea-level to 1000 m; in SE Russia below 150 m and in Japan below 800 m; during spring migration in Peninsular Malaysia mostly below 800 m, sometimes above 900 m.

Food and Feeding. Almost exclusively insects, mostly Orthoptera and beetles (Coleoptera); rarely, small birds and other small vertebrates (frogs, lizards and rodents). Forages singly, in pairs or in family parties. Rather inconspicuous, keeping more to the forest than most other members of family. Hunts in unusual manner, by skulking at all levels of trees and bushes and gleaning from branches and leaves; hunts also in typical shrike fashion, hawking for insects from exposed perch.

Breeding. Season May–Jul, and laying starts Jun in Russia and Japan; single-brooded. Monogamous; territorial. Nest a compact, thick cup made of weeds, grasses, twigs, roots, pliable bark and other vegetable material, lined with fine grass, seeding grass-heads and fresh leaves, average external diameter 13 cm, height 7.5 cm; placed 1.5–6 m (sometimes higher) above ground on horizontal branch, 1.5–4 m from trunk, in deciduous tree such as oak, elm or apple (*Malus*), in S of range also in bramble (*Rubus*) or low bush. Clutch 3–6 eggs, mostly 5 (mean in Russia 5.3), variable in colour, whitish to bluish-green or pale orange with brown, grey or violet spots, patches and streaks, chiefly at large end; if clutch lost, replacement frequently recorded; incubation by female, period 15–16 days; nestling period c. 14 days; juveniles remain in parental territory for a further 14 days.

Movements. Migratory, although few remain in Japan. N limits of non-breeding range just S of S limits of breeding range. Leaves Russian breeding grounds in Aug, returning end May to mid-Jun; Japanese breeders depart Aug–Sept, returning May. Scarce to uncommon passage migrant and probably also winter visitor in SE China, E & S Myanmar, N, C & S Thailand, N Laos and Vietnam; fairly common to common passage migrant and winter visitor in Peninsular Malaysia (late Aug to early May), Singapore and surrounding islands, and Sumatra (recorded between 3rd Sept and 22nd Apr); scarcer and more irregular in Java and Bali. In Peninsular Malaysia, passage migrants mist-netted at Fraser’s Hill from 9th Sept to 2nd Nov and from 11th Apr to 7th May. Vagrants recorded Hokkaido, in N Japan (during summer months), and on some offshore Japanese islands, also in Hong Kong (Sept), Philippines (Apr), and Sulawesi.

Status and Conservation. Not globally threatened. Few precise data on population size and trends; locally fairly common, but rare in some parts of range. Status in S Japan (on most parts of Kyushu, Shikoku and Tsushima) not known. Range estimated at more than 1,000,000 km². N populations have declined considerably over last 30–40 years, now rare in SE Russia and NE China; in Japan once common and widespread, even in suburban parks in Tokyo, but now very local and uncommon. Fairly common breeder in E China and Korea. Local and scarce to fairly common in non-breeding range. Densities generally low; estimated 1 pair/2.5–3 km² in far N of range, although some nests here are only 10–12 m apart.

Bibliography. Brazil (1991), Chen Fuguan *et al.* (1998), Dementiev *et al.* (1954b, 1968), Étiénnecopar & Hùe (1983), Flint *et al.* (1984), Harris & Franklin (2000), Imanishi (2007b), Jeyarajasingam & Pearson (1999), Kennedy *et al.* (2000), Kryukov (1995), Lefranc & Worfolk (1997), MacKinnon & Phillips (1993, 2000), Meyer de Schauensee (1984), Ohata (1991), Panov (1983, 1995, 1996), Robson (2000b), Sheldon *et al.* (2001), Smythies (1986), Tomek (2002), Wells (2007), Yan Chongwei & Xu Weishu (1996).

2. Bull-headed Shrike

Lanius bucephalus

French: Pie-grèche bucephale **German:** Büffelkopfwürger **Spanish:** Alcaudón Bucéfalo
Other common names: Highland Shrike (Japanese populations)

Taxonomy. *Lanius bucephalus* Temminck and Schlegel, 1845, Japan.

Probably closest to the superspecies formed by *L. collurio*, *L. isabellinus* and *L. cristatus*. Two subspecies recognized.

Subspecies and Distribution.

L. b. sicarius Bangs & J.L. Peters, 1928 – breeds S Gansu, in C China.

L. b. bucephalus Temminck & Schlegel, 1845 – breeds SE Russia (Ussuriland), NE China (S Manchuria S to Hebei and Shandong), Korea, S Sakhalin I, S Kurils, Japan (including many smaller islands), Ryukyu Is, Daito Is and Ogasawara Is (Bonin Is); non-breeding also E & SE China.

Descriptive notes. 19–20 cm; male 35–46 g, female 34–52 g. A medium-sized shrike with relatively long tail. Male nominate race has rufous crown, black facial mask from lores back to rear side of neck, narrow white supercilium (individually variable), greyish-rufous nape; upperparts greyish; upperwing mostly black, primaries with conspicuous white patch at base, inner secondaries and tertials fringed greyish, upperwing-coverts slightly fringed whitish; uppertail grey, central feather pair darker, fresh rectrices have white tip and black subterminal band; chin and throat off-white, underparts bright orange-buff, whiter on centre, side of

breast and flanks often faintly barred or scaled brown, undertail-coverts and underside of rectrices brownish-grey; iris dark brown; bill black, base of lower mandible yellowish or pinkish-white in non-breeding season (turns black in breeding season), palate deep red; legs black. Female has crown burnt umber, facial mask dark brown (mask sometimes absent on individuals on Minami-daito I), buff supercilium individually variable in width and length, greyish-umber nape and upperparts; rectrices greyish-umber; upperwing similar to male, but no white primary patch (or sometimes a very narrow one), secondaries and tertials dark brown, inner feathers fringed rufous-brown, wing-coverts dark brown and slightly fringed rufous-brown; chin and throat off-white, underparts washed brown-buff and heavily vermiculated dark brown, undertail-coverts brown-buff, underside of tail light brown, rectrices with white tip and black subterminal band; bare parts as male. Juvenile has dark brown facial mask, small buff supercilium over eye, crown and upperparts dark-barred rufous-brown, tail dark brown, flight-feathers and upperwing-coverts mainly dark brown, inner secondaries and tertials fringed rufous-brown, greater coverts slightly fringed rufous-brown, median and lesser coverts barred brown, primary coverts and alula with buff tips or fringes; young male has white primary patch, lacking on female; chin and throat off-white with faint barring, underparts brown-buff with heavy dark brown vermiculations (dark subterminal bands on each feather), undertail-coverts unbarred, underside of tail light brown, rectrices with white tips, outer rectrices fringed white. Race *sicarius* male has darker grey back and less conspicuous white wing patch than nominate, female has heavier vermiculations on flanks than nominate female, both sexes lack pale collar at base of bill. Voice. Male song, from top of tree or utility pole, a repeated trilling “gyun-gyun-gyun”, sometimes “kyurururururu” in flight early in morning. Female gives “jiá-jiá-jiá” call, like begging call of nestling, with wing-fluttering; male gives same “jiá-jiá-jiá” call, also with wing-fluttering, before copulation. Male, especially, imitates vocalizations of other birds, e.g. Brown-eared Bulbul (*Microscelis amaurotis*), Japanese White-eye (*Zosterops japonicus*), Brown-headed Thrush (*Turdus chrysolaus*), Oriental Greenfinch (*Carduelis sinica*), Latham’s Snipe (*Gallinago hardwickii*), and even insects such as cicadas (Cicadoidea) in breeding season. Both sexes give trilling calls in autumn.

Habitat. Wide range of open habitats, e.g. farmland, suburban parks, gardens in villages, areas with scattered shrubs, hedgerows, shelter-belts, and forest edge. Some individuals winter in woodland, which in N Japan (Hokkaido) is completely snow-covered in that season. From near sea-level to 2700 m; breeding to c. 1500–1800 m in C Honshu, in Japan. In C China, race *sicarius* found in highlands from 1000 m to 2150 m.

Food and Feeding. Invertebrates, especially beetles (Coleoptera); also small vertebrates; some seeds also taken. In study in C Japan (Shizuoka), 49 pellets during breeding season contained 393 prey remains composed of insects (of eight orders, 24 families, 34 genera) and frogs, of which beetles (mainly of genera *Amara* and *Anisodactylus*) represented 72% (283 items), Orthoptera (of genus *Gryllotalpa*) 7.6%, and Hymenoptera (of genera *Cyphononyx*, *Vespa*, *Polistes*, and *Apis*) 6%; in winter, 102 pellets contained 1077 items, consisting of insects (eight orders, 23 families, 36 genera), woodlice (Isopoda), spiders (Araneae), centipedes (of genus *Scolopendra*), birds, rodents, and seeds of *Eucynimus japonicus* and *Ligustrum japonicum*, with beetles (of at least five genera) 51.7% of total and Hemiptera next in frequency (13.8%). Of 731 items detected in stomach analyses of 116 individuals, larvae of weevils (Curculionidae) represented 23.5%, and adult beetles only 6.8%; remains of birds and rodents also found in stomachs. Of 88 impaled prey, locusts 70.5%; other impaled prey included small fish e.g. loach (Cobitidae), amphibians, reptiles, birds e.g. Eurasian Tree Sparrow (*Passer montanus*), Black-faced Bunting (*Emberiza sspodicephala*), Great Tit (*Parus major*), Japanese Bush-warbler (*Cettia diphena*), Oriental Greenfinch and Daurian Redstart (*Phoenicurus aureus*), and mammals e.g. shrews (Soricidae) and rodents. In Chiba (C Japan), 88% of prey during nestling period in Jul consisted of arthropods, e.g. the robber fly *Promachus yesonicus*, the orthopteran *Atractomorpha bederi*, tabanid spiders, adult Lepidoptera, etc., and 12% of vertebrates (Tree Sparrows and reptiles). On Hokkaido (N Japan), arthropods constituted 95% of all prey delivered to nestlings (i.e., Lepidoptera larvae 34.5%, Orthoptera 30.3%, Arachnoidea 16.4%); of 129 impaled prey items in autumn and winter, frequency of reptiles 7.8% (of amphibians 9.3% and of fish 9.3%, with remainder of prey invertebrates, mainly Locustidae (21.5%) and Lepidoptera larvae (12.4%). On Sakhalin I, prey items by pellet analyses were mainly beetles, Hymenoptera (bumblebees, wasps), lizards (Lacertidae), rodents, shrews and birds, e.g. Siberian Rubythroat (*Luscinia calliope*), Middendorff’s Warbler (*Locustella ochotensis*), Oriental Greenfinch, etc. Forages singly and in pairs. Hunts from fairly high perches, including utility wires and fences, from which it pounces on prey on ground. Maintains lairs.

Breeding. In Japan, laying from Apr to Jul in N (Hokkaido) and, in C regions, from early Mar to late Jun in Mie and from late Feb to late Jul in Osaka, and breeds late Jan to Aug on Minami-daito I;

breeds May–Jul in C China (race *sicarius*); occasionally double-brooded, e.g. 10% of pairs that had bred successfully initiated a second nesting attempt. Monogamous; territorial, home range variable according to availability of perching sites, in one study 0.92–4.29 ha. Courting male moves raised head and tail to right and to left, and pursues female while displaying the white patch on wing. Nest an open cup made from twigs, bark, moss, leaves and grass stems, lined with rootlets, hair and other fine material, external diameter 12.5–16 cm, height c. 10 cm, internal diameter 7–8 cm, depth c. 7 cm, placed c. 0.3–4.5 m above ground in bush or tree, often surrounded by thorns and/or nettles (*Urtica*), on Minami-daito I mainly in evergreen tree *Calophyllum inophyllum* at mean height of 2.52 m; on Hokkaido, nest built at average of 0.75 m in dwarf bamboo or vine bush in early breeding season, but at average of 1.35 m in variety of green deciduous shrubs later in season. Clutch 2–7 eggs, usually 5 or 6 (3–6 on Hokkaido and in S Ussuriland, mode 5 on Minami-daito I), in C China (race *sicarius*) 4–6, colour variable, e.g. buff with fine dark brown spots or reddish-white with fine reddish-brown spots; incubation by female, fed on nest by male, period 13–16 days, generally c. 15 days (*sicarius* 14–15 days); chicks brooded by female for first week, fed by both parents, in one study hourly feeding rates (number of deliveries per nestling) when chicks 6 days were 1.9 by male and 0.92 by female, and when chicks 12 days were 2.1 by male and 2.6 by female; nestling period c. 13–15 days (13 days for C China race *sicarius*); fledglings fed by parents for at least 15 days after leaving nest. Nests parasitized by Common Cuckoo (*Cuculus canorus*) and Horsfield's Cuckoo (*Cuculus horsfieldi*). First breeding, by both sexes, at 1 year. Longest recorded lifespan in Japan 8 years 1 month (female) and 5 years 11 months (male).

Movements. Migratory, partially migratory and resident. Summer visitor in SE Russia, Sakhalin and NE China, moving to non-breeding grounds mainly in E & SE China, Korea and C & S Japan; arrival from Apr. departure Aug–Sept, occasionally not until early Oct (e.g. S Sakhalin). Mainly resident in S & SE of range, including islands. In Japan, mostly migratory on Hokkaido and N Honshu, whereas populations S of there are more or less sedentary or undertake local movements; some of latter, however, winter in N Honshu and even Hokkaido; altitudinal movements also recorded, with descent from higher elevations of Honshu (800–1800 m). Race *sicarius* apparently resident in C China.

Status and Conservation. Not globally threatened. Not uncommon in much of range; declining. Nominate race declining in Japan, where breedings pairs observed at less than half the number of sites in 1990s compared with 1970s; has disappeared from 134 sites in the last three decades in Tokyo, and only 44 reported as as occupied in 1990s, this decrease correlated with shrinkage of farmland in Tokyo; in a study area on Hokkaido, number of pairs approximately constant over the four years 1993 to 1996, but almost certainly reduced more recently by opening of a large roadway in area. This species appears certainly likely to be threatened by developments in the near future in Japan. Rare on Sakhalin I; no information on status of nominate race in rest of range, but considered probably fairly secure, at least in the short term. Occurs Pangqiangou National Nature Reserve, in NE China (N Shanxi). No accurate details of population size of race *sicarius*, but likely to be very small, and distribution of this taxon very restricted within narrow area of C China.

3. Red-backed Shrike

Lanius collurio

French: Pie-grièche écorcheur **German:** Neuntöter **Spanish:** Alcaudón Dorsirrojo

Taxonomy. *Lanius collurio* Linnaeus, 1758, Europe = Sweden.

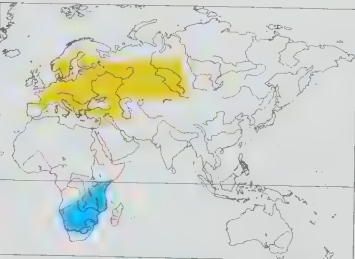

Thought to form a superspecies with *L. isabellinus* and *L. cristatus*; has in the past been considered conspecific with one or both of those, but recent genetic analyses support treatment as separate species. Degree of reproductive isolation between this species and *L. isabellinus* relatively low, and mixed pairs and hybrids regularly occur where ranges overlap in SW, W & C Asia; occasional hybridization with *L. cristatus* in C Asia. Races intergrade; *pallidifrons* and *kobylini* possibly result from influence of these two neighbouring species, and are individually strongly variable, such that recognition of either is dubious; species perhaps better treated as monotypic. Additional proposed race, *juxtus* (described from east Suffolk, in E England), is indistinguishable from nominate. Three subspecies tentatively recognized.

Subspecies and Distribution.

L. c. collurio Linnaeus, 1758 – breeds Europe (except N, NW & SW) E to W Siberia, S to N Iberia, Sardinia, S Italy, Sicily, Balkans (S to Croatia), C Romania, Ukraine, and plains N of Caucasus; non-breeding S & E Africa.

L. c. kobylini Buturlin, 1906 – breeds Balkans (S from Bosnia) E to Crimea and Caucasus, S to Asia Minor, Cyprus and NW Iran; non-breeding S & E Africa.

L. c. pallidifrons H. C. Johansen, 1952 – breeds W & WC Siberia (E to NW Altai); non-breeding S & E Africa.

Descriptive notes. 17 cm; 22.5–34 g. Rather small shrike with fairly short wings and longish tail; when excited, indulges in tail movement in form of loose flick or curving swing, accompanied by partial spreading of tail. Male nominate race has bluish-grey upper forehead and crown to nape and hindneck, black lower forehead and mask from lores to rear of ear-coverts; mantle, scapulars and back bright chestnut, rump and uppertail-coverts bluish-grey; upperwing blackish, feathers edged chestnut, sometimes a very small white patch at base of primaries; tail black, all except central pair of feathers with white base, outermost

greyish (variable, some with head pattern more like male); rump and uppertail-coverts grey to greyish-brown, tail dark brown to rufous-brown with whitish edges and tip (variable, some with tail like that of male), upperwing as male but fringes paler and duller; creamy below, often with pale pinkish-buff wash on side of breast and flanks, vermiculated with blackish (except on throat and undertail-coverts); bare parts as male, but bill and legs slightly paler. Juvenile is similar to female but with even less contrast in plumage, entire upperside, including top of head, rump, upperwing-coverts and tertials, rufous-brown to buffish-brown with heavy blackish crescentic barring, underside more heavily vermiculated than female. Races differ little, are also individually variable: *kobylini* is somewhat duller than nominate, usually with greyer upper mantle; *pallidifrons* has paler crown and hindneck than nominate. VOICE. Main call a hoarse, muffled “gä”, “gwä” and “krew”, or rougher “gek, gek”, also as shorter “tek-tek” for contact; during excitement varied to “tschä” or “tschäck”, which can end in alarm call, “dschrää-dschrää...”. Male gives “tschok” call for marking territory and simultaneously attracting females; “hiää” calls by food-begging female, as well as nestlings. Male song (without territorial function) during display a soft warble, incorporating songs and calls of a wide range of other bird species (learned during immature imprinting between leaving nest and autumn migration, thus no birds from winter range imitated), in Middle Europe most common songs copied from Common Blackbird (*Turdus merula*), Great Tit (*Parus major*), European Crested Tit (*Lophophanes cristatus*), Barn Swallow (*Hirundo rustica*), *Acrocephalus* warblers, *Sylvia* warblers, *Emberiza* species, and calls of Common Chaffinch (*Fringilla coelebs*) and White Wagtail (*Motacilla alba*), also of non-passerines such as Grey Partridge (*Perdix perdix*), Common Quail (*Coturnix coturnix*) and Little Grebe (*Tachybaptus ruficollis*); no clear verses or repetitions, and most verses introduced and closed with “dschä”-calls; songs can last for more than 10 minutes without pause.

Habitat. Requires sunny, warm, usually dry, and level or gently sloping terrain, with scattered bushes, shrubs or low trees (1–3 m tall) providing hunting posts overlooking areas of short grass, heath or bare soil (suitable for small prey); high-quality habitats tend to feature mosaic-like grassy vegetation with alternating areas of tall and short growth and bare areas, with perches. In agricultural areas occupies neglected overgrown patches, heaths, open downs, overgrown orchards and gardens, hedgerows, and scrub along railways or roadsides; found also in temporary steppe-like habitats, e.g. military training areas, burned forests, forest clearings and spruce (*Picea*) plantations. In W Europe associated mostly with cattle breeding, as often found in hilly regions or at middle altitudes. Regular near agricultural roads, as these combine easy prey accessibility (bare ground, regularly mown road edges) with fence posts for perches, scattered shrubs or hedges for breeding, and unmown vegetation as prey habitat. Sometimes occupies atypical habitat when breeding pairs “clumped” in loose colonies. Avoids very dry areas, and confined to mountainous areas in N Iberian Peninsula; in Alps ascends mostly to 1000 m, exceptionally 2050 m; in Caucasus usually to 2000 m, less often on subalpine meadows to 3200 m; to 1400 m in Sicily. On S African wintering grounds occupies habitats with vegetation structure similar to that in breeding quarters; occurs widely in savanna, and extends into other grasslands and karoo. In N South Africa shows preference for low scrub (1–3 m tall) and open bush (10–50% coverage); uses perches 1.5–3 m high in open areas with herbaceous layer rich in insects.

Food and Feeding. Opportunistic, taking mainly insects, especially beetles (Coleoptera), Orthoptera and Hymenoptera, also other invertebrates; also small mammals, mostly voles (Microtini), birds, and reptiles; at end of summer and in autumn diet sometimes complemented by berries, especially of wild cherry (*Prunus avium*) and elder (*Sambucus nigra*). Great majority of bird prey are nestlings and fledglings; adult birds taken are generally weak or injured, and any healthy ones probably taken at nest. Small or soft prey regularly fed to small nestlings. Most prey located from exposed, usually low perch, by sit-and-wait strategy. Large moving insects spotted up to 30 m away, and caught in bill after shallow direct glide, which may terminate in brief hover before bird drops into vegetation; also drops straight on to prey below perch. Flying insects taken in rapid, sometimes lengthy, aerial pursuit. Prey (even small items) almost always carried back to perch for consumption or impaling. Many prey items impaled on thorns, broken twigs, barbed wire, etc., in caches (larders), although individual items may be widely scattered throughout territory. Deals with invertebrate prey by beating them on substrate to remove extremities, wingcases, etc., or picks these off by bill while holding prey under, or in, foot or after impaling. Vertebrate prey killed by blow to back of head or neck; brain often consumed on ground and animal decapitated before being cached. Unable to dismember vertebrate prey held only under foot, and these therefore impaled for treatment.

Breeding. Laying from early May or mid-May (according to latitude) to Jul; usually one brood, rarely two (two recorded in Belgium, France and Germany). Pair formation fairly rapid, mostly in breeding territory, although occasionally during spring stopovers. Nest untidy-looking, a loose foundation of often green plant stems (some thick or woody), roots, grass, lichen, hair, etc., compactly lined with grass, hair, moss, fur, reed (*Phragmites*) or reed-mace (*Typha*) flowerheads, plant down and similar material, situated at 0.3–5 m but generally low down (1–1.5 m on average) in dense, often thorny bush such as hawthorn (*Crataegus*), blackthorn (*Prunus spinosa*), bramble (*Rubus*) or dog-rose (*Rosa*). Clutch 1–8 eggs, mostly 3–7, in W Europe first clutches usually 4–6 eggs (7-egg clutches much more frequent in E than in W), clutch size decreases during course of season; replacement clutches contain fewer eggs on average, eggs very variable, subcylindrical to oval, very slightly glossy, pale green to pinkish or creamy white with band of light brown, olive, brownish-red, grey or purple specks and small blotches near broad end (markings sometimes scattered over whole surface, or even present only at narrow end); several replacement clutches may be laid (particularly in second half of Jun) if earlier ones lost; incubation almost exclusively by female, although rarely male assists, period 12–16 days, mostly 14 days; chicks brooded by female and fed by male for first week, thereafter fed by both sexes; very occasionally, one or more unmated individuals help in brood-rearing, at times taking over almost entire task from breeding pair; nestling period normally 14–16 days, sometimes longer (up to 18–20 days) in very bad weather, or sometimes predators cause young to jump out of nest when only 11 days old; fledglings begin to catch insects for themselves from c. 14 days after leaving nest, become independent c. 20 days later.

Movements. Migratory; non-breeding range in E & S Africa S from extreme S Somalia (rare) and SE and coastal Kenya, but main bulk of population S from Zambia and Malawi. N passage in spring following more E course than autumn passage, and notable for concentration of migration routes across and around E end of Mediterranean, even by populations breeding in extreme W of Europe. Nocturnal migrant. Leaves breeding grounds from late Jul, mostly in second half Aug and early Sept, general direction of movement SE or SSE towards E Mediterranean; those crossing Mediterranean Sea make landfall on N African coast almost entirely E of 20° E; passage through Egypt mainly mid-Aug to early Nov, first arrivals in extreme S of wintering areas in late Oct. Return migration from winter quarters begins second half Mar, all having left extreme S by about middle of Apr; more E course of N migration evident in E Africa, and divergence between spring and autumn routes more pronounced farther N. Arrival on breeding grounds in Apr in N Israel, mostly May in Europe; males generally reach breeding areas a few days before females (up to five days earlier in Europe).

Status and Conservation. Not globally threatened. Locally common to uncommon or rare. European breeding population estimated as exceeding 6,300,000 pairs, but underwent moderate decline

pair with white outer web (in flight, all-black central tail feathers and black terminal band on others form inverted T-shape on white background); chin and throat white, underparts very light salmon-pink, undertail-coverts white, sometimes some dark barring on flanks (present on 4% of males trapped in Germany); iris dark brown; bill black or blackish, paler or bluish base in non-breeding season; legs black or dark brown. Female is similar to male but generally paler and duller, with creamy lower forehead and supercilium and brown ear-coverts (facial mask thus restricted and much less distinct), crown and upperparts warm brown or greyish-brown, nape usually tinged

between 1970 and 1990; although declines continued in several countries during 1990–2000, most E populations remained stable. Species probably declined only slightly overall, and is provisionally evaluated as “depleted”. Range has contracted in Iberia, Belgium, Netherlands, Denmark, and Ukraine, but has expanded in Norway. More or less extinct in Britain (formerly locally common in England), but recently bred N Scotland (Shetland). Elsewhere, numbers greatly reduced in many areas, but without apparent reduction of range on broad scale. Decline probably due mainly to loss and fragmentation of habitat resulting from afforestation and agricultural intensification, increased use of pesticides causing loss of food resources. In N & W edges of range, breeding affected by cooler, wetter summers. Increase in 1990s observed in W Europe, and resulted in recolonization of a restored peat-bog reserve (Bargerveen) in Netherlands, where this species increased from a few pairs in 1970s to 105 pairs in 1992. Spread in S & W Norway since 1970s, and expanded N in Sweden 1970–90. Small isolated populations nest in mountainous areas of W Syria (Anti-Lebanon), N Israel (Mt Hermon) and Lebanon.

4. Isabelline Shrike

Lanius isabellinus

French: Pie-grièche isabelle **German:** Isabellwürger **Spanish:** Alcaudón Isabel
Other common names: Rufous-tailed/Red-tailed Shrike, Central Asian/Pale-brown/Daurian Shrike; Turkistan (Red-tailed) Shrike (*phoenicuroides*)

Taxonomy. *Lanius isabellinus* Hemprich & Ehrenberg, 1833, Gumduda (= Al Qunfidhah), Arabia. Thought to form a superspecies with *L. collurio* and *L. cristatus*; has in the past been considered conspecific with one or both of those, but recent genetic analyses support treatment as separate species. Degree of reproductive isolation from former relatively low, and mixed pairs and hybrids regularly occur where ranges overlap in SW, W & C Asia. Nomenclature of races recently revised, as true identity of nominate *isabellinus* had been confused: race *arenarius* previously treated as nominate until examination of the type specimen of *isabellinus* (collected on non-breeding grounds in W Arabia) showed it instead to be identical to the form hitherto listed as *speculigerus*; as a result, form previously known as *speculigerus* becomes nominate, with name *speculigerus* as a synonym, while form previously treated as nominate takes the oldest available name applicable to it, *arenarius* (see page 733). Races form two groups, nominate and *phoenicuroides* representing one group and *arenarius* and *tsaidamensis* the other; these groups treated by some Russian authors as two separate species, but nominate race probably intergrades with *arenarius* in N China (S Nei Mongol). Proposed race *karelini* (from S Kazakhstan) included within *phoenicuroides*. Four subspecies recognized.

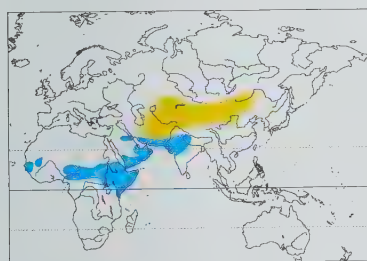

Subspecies and Distribution.

L. i. phoenicuroides (Schalow, 1875) – breeds S & E Kazakhstan S to Transcaspiya, NE & E Iran, Afghanistan, Pakistan (N and probably W of R Indus) and extreme NW China (NW Xinjiang); non-breeding mainly Arabia and NE & E Africa, with some in W Africa.

L. i. isabellinus Hemprich & Ehrenberg, 1833 – breeds Mongolia (except NW) and S & E Russian Transbaikalia S to NW & N China (SE Altai and NE slopes of Tien Shan, in NE Xinjiang, E to C Nei Mongol); non-breeding mainly Arabia and NE Africa.

L. i. arenarius Blyth, 1846 – breeds W & NC China from SE slopes of Tien Shan and Tarim Basin E to NW Gansu and W Nei Mongol, S to Ningxia; non-breeding mainly Pakistan and N India.

L. i. tsaidamensis Stegmann, 1930 – breeds WC China (Qaidam Basin, in N Qinghai); non-breeding mainly Pakistan and N India.

Descriptive notes. 17.5–18 cm; 25–34 g. Rather small, compact but long-tailed shrike, with calls and behaviour as *L. collurio*. Male nominate race has pale greyish crown, tinged isabelline on forehead, complete black facial mask with narrow whitish border above, rather warm sandy grey on upperparts to upper rump, rufous lower rump and reddish-brown tail; upperwing contrastingly blackish, feathers edged pale sandy buff, white patch at base of primaries; throat whitish, underparts sandy cream to isabelline; iris brown; bill dark brown to dull blackish; legs grey-black. Female resembles male but slightly duller, with browner

and less extensive facial mask, smaller patch at base of primaries (sometimes absent), slightly scaled underparts, and pink bill base, legs browner or greyer. Juvenile is greyish-brown with narrow blackish vermiculations above, tail rufous-brown, creamy buff with brownish vermiculations below, throat and narrow band down to undertail-coverts generally plainer; first-winter has remnants of juvenile barring above and below, whitish-buff supercilium, brown ear patch, subterminal dark bars on tertials, lower rump, uppertail-coverts and tail, white patch on base of primaries little developed. Races differ mainly in coloration and size: *phoenicuroides* is darker than nominate, male has crown tawny to rufous, upperparts buffish-brown, usually bolder white supercilium, and whiter below with vinous-pink wash on flanks, variable, some (mainly in lowlands) closer to nominate, with greyer crown and upperparts, less prominent supercilium, and buff-tinged underparts (“*karelini*”); *arenarius* has relatively shorter and less pointed wing than previous and nominate, is also pale, male uniform greyish or sandy grey above, less well-defined facial pattern, pale lores, pale primary patch small and less white, tail dull cinnamon (less rufous), underparts sandy pinkish to pale buff, whiter on centre of belly; *tsaidamensis* is very like last but longer-winged and slightly paler. **VOICE.** Considered a much better singer than *L. cristatus*, and calls somewhat reminiscent of those of *L. collurio*, but courtship calls more nasal “tschre...tschre...” (race *arenarius*) and “zauzat-zauzat...” (*phoenicuroides*), while contact call of nominate “kscha-kscha”. Male territorial calls described as “tsch-ef...tsch-ef”, “zech-zeck” and “zea-zea”, but in presence of mate change to “ko-ick”, and “zauzat...zauzat” and “tzauzat...tzauzat”, respectively. When disturbed, “zeec” or sometimes “dzikhk-dzhikhk-dzhikhk”; wide variety of alarm calls reported, from typical “ktschaaa” and chattered “chak-chak-chak” to rattling “krkrkrkr...”, “tschek-tscheck” can be given as alarm, as

well as during courtship. Intraspecific begging calls of mates are series of “kikikiki...” or “keee-keee-keee” (nearly identical to begging calls of juveniles). Song said to be a relatively quiet warble, often replaced by harsher and squeaker melodies; mimics other birds.

Habitat. Breeds in tamarisk (*Tamarix*) thickets in river valleys, patches of scrub in dry steppe, in mountains extending up to zone of prostrate juniper (*Juniperus*), e.g. in S Turkmenia; on hills and barren plains, and in mountains to 3500 m (Pamir Mts, in Tajikistan). In non-breeding quarters, found in India and Pakistan on edges of cultivation in semi-desert and among sparse acacia (*Acacia*) and tamarisk trees, often in open grassland near water; in E Africa occurs in relatively open country with scattered bushes, and in dry lowlands, generally preferring drier and more thorny vegetation than that used by *L. collurio*, but in Chad observed in marshy areas. As with other shrikes, from several of which it seems not to be segregated in winter quarters, foraging requirements include much exposed soil.

Food and Feeding. Almost exclusively insectivorous. Prefers mostly beetles (of families Elateridae, Tenebrionidae, Scarabaeidae) and crickets and grasshoppers (Orthoptera), with other invertebrates taken less often; also some small vertebrates taken, including voles (Microtini), lizards, and small birds such as leaf-warblers (*Phylloscopus*). Uses sit-and-wait foraging technique, utilizing a variety of lookouts, including wires, fence lines and tree branches; mean height of perch 2.1 m on non-breeding grounds in Kenya. Most insects taken on ground (73% of 175 prey items in Kenya). Impaling of prey not rare.

Breeding. Laying end of Apr in S of range (S Turkmenistan) to end May in N (Kazakhstan, Altai); one brood. Mating normally begins with loud calls by male, which often followed by gliding display-flights of competing males; male has aerial display, flying to and fro in front of female while calling loudly, also bowing perched display with fanned tail raised, this often followed by fluttering flight by both partners. Nest-site chosen by male; nest a deep open cup made from twigs, bark, rootlets, leaves and grass, lined with grass stems, moss and similar soft material (resembles nest of *L. collurio*), built c. 0.3–5 m but generally low (mean 1–2 m) above ground in bush, often thorny one. Clutch 3–7 eggs, mostly 4–6 (mean 5 in N Iran), pale bluish-green, with light-brown spots concentrated toward broad end; replacement clutches frequent if earlier ones lost; incubation by female, fed on nest by male, period 13–17 days; nestling period 13–16 days; young fed by parents for c. 1 month after leaving nest. Nests regularly parasitized by Common Cuckoo (*Cuculus canorus*), e.g. 14.5% of 90 nests of race *phoenicuroides* in L Balkash area of Kazakhstan. Breeding success in Tajikistan relatively low, c. 53% of nests failed during incubation stage. First breeding at 1 year of age.

Movements. Migratory. Non-breeding grounds from sub-Saharan Africa (mostly E from Nigeria, S to NE Tanzania) and Arabia E to Pakistan and NW India; present in winter quarters Nov–Mar, in extreme cases from Oct and up to May. Heading in autumn varies between SW (most *phoenicuroides*, fewer nominate) to Arabia and Africa, and S to SE to Iraq, S Iran, Pakistan and India (most *arenarius* and *tsaidamensis*); regular autumn passage migrant through Iraq in Sept. Those wintering in Nigeria must head almost due W within Africa; in addition, *phoenicuroides* is a rare winter visitor also in W Africa (Senegal, Gambia, Mauritania). Return migration in spring apparently along same routes as used in autumn; peak spring movement in NE Africa mid-Apr, in NW India in Mar; occasional in Israel and NE Egypt (Sinai) in spring. Breeding population of *phoenicuroides* arrives in Turkmenia from early Mar to early Apr, and nominate race reaches S Mongolia at end May; males arrive on breeding grounds earlier than females. Vagrants recorded increasingly in Europe, even in NW (Britain), mainly in autumn.

Status and Conservation. Not globally threatened. Not well known; probably not uncommon in much of range, but locally uncommon. Global population size not quantified, but believed not to be close to the thresholds that would indicate that this species is at risk. Protected in most countries; in some listed as “endangered”. A decrease in the use of agricultural pesticides, combined with conservation of semi-open habitats (pastures, meadows) with scattered bushes, would probably be the most effective measure to ensure its future. Present in several national parks and other protected areas in its non-breeding range.

(2006), Shirihai (1996), Stepanyan (2003), Welch & Welch (1984), Zhang Wei *et al.* (2007).

5. Brown Shrike

Lanius cristatus

French: Pie-grièche brune **German:** Braunwürger **Spanish:** Alcaudón Pardo
Other common names: Red-tailed Shrike; Japanese Shrike (*supercilius*); Philippine Shrike (*lucionensis*)

Taxonomy. *Lanius cristatus* Linnaeus, 1758, Bengal, India.

Thought to form a superspecies with *L. collurio* and *L. isabellinus*; has in the past been considered conspecific with one or both of those, but recent genetic analyses support treatment as separate species. Occasional hybridization with *L. collurio* recorded in C Asia. Geographical variation partially clinal; race *confusus* poorly differentiated, intergrades with nominate and perhaps better merged with it. Four subspecies currently recognized.

Subspecies and Distribution.

L. c. cristatus Linnaeus, 1758 – breeds C & E Siberia S to N Mongolia, L Baikal area, N Sakhalin and W Kamchatka; non-breeding C & S India, Sri Lanka, Bangladesh, Myanmar (mainly coastal) and Malay Peninsula.

L. c. confusus Stegmann, 1929 – breeds E Mongolia, SE Russia (SE Transbaikalia E to Amurland and Ussuriland) and Manchuria; non-breeding S Malay Peninsula and Sumatra.

L. c. superciliosus Latham, 1801 – breeds S Sakhalin I, S Kuril Is and N & C Japan (Hokkaido, N & C Honshu); non-breeding mainly coastal S China, Hainan, NE & E Indochina, Sumatra, Java and W Lesser Sundas.

L. c. lucionensis Linnaeus, 1766 – breeds E China, Korea and S Japan (Kyushu); non-breeding mainly coastal SE China, Taiwan, Philippines, N Borneo and N Sulawesi.

Descriptive notes. 17–20 cm; male 27–34 g, female 28–37 g. A medium-sized shrike with rather large head. Male nominate race has black facial mask from lores back to rear ear-coverts, broad white supercilium; lower forehead buffish-white, becoming dull brown on forehead, rufous-brown crown to nape, very slightly duller russet-brown upperparts, but rump and uppertail-coverts a little brighter (as crown); upperwing dark brown, wing-coverts and inner flight-feathers fringed whitish; tail dull rufous, outer feather pair edged and tipped paler; throat white, underparts whitish with pale rufous wash, undertail-coverts pale brownish-grey; iris brown; bill and legs black or blackish. Female is very like male, and sometimes identical, but generally supercilium creamy-tinged, dark mask slightly less distinct in loreal area, and side of breast and flanks with fine dusky vermiculations; in non-breeding season bill usually duller, with pinkish base. Juvenile has supercilium duller and

blurred, facial mask brown and less extensive, top of head and upperparts rufous with heavy cinereous-brown barring, upperwing brown, wing-coverts, secondaries and tertiaries fringed rufous-buff, tail as in adult, throat whitish, cheek and underparts buff with heavy dark vermiculations, centre of belly to vent usually plain. Races differ mainly in plumage coloration and pattern: *confusus* is very similar to nominate, but male has upperparts somewhat paler and greyer and pale band on forehead broader, female has pale rufous upperparts; *superciliosus* is distinctive, brighter than others, male has wider white band on forehead

merging with broad white supercilium, strongly contrasting jet-black mask from bill base to near nape, bright rufous crown, nape and upperparts, wing edgings rufous (not buff or whitish), sometimes a very small white patch at base of primaries, underparts more orange-tinged, female duller than male, with white frontal band and supercilium narrower, never has pale primary patch, flanks paler and slightly vermiculated: *lucionensis* also is distinctive, much greyer than others and with narrower supercilium, male has light grey crown and nape, brownish-grey upperparts except for russet-brown rump and uppertail-coverts, buff belly and flanks to undertail-coverts, female somewhat paler than male, has mask blackish-brown (not jet-black), supercilium less distinct. **VOICE.** Male song a repeated trilling "jun-jun-jun" and/or "kichi-kichi-kichi" and/or "gey, gey, gey" as it moves around tops of trees; male imitates songs and calls of other birds, e.g. Japanese White-eye (*Zosterops japonicus*), Azure-winged Magpie (*Cyanopica cyanus*) and White-cheeked Starling (*Sturnus cineraceus*). During mate attraction, male pursues female while uttering trilling subsong. Female calls "jih-jih-jih", like begging call of nestling, with wing-fluttering.

Habitat. Generally in open areas with bushes and scattered small trees, but variable; sometimes in urban parks. Nominate race breeds mainly in taiga, tundra forest and tundra edge, in bogs and boggy meadows with scattered trees, often in burnt areas, in Kamchatka in grassland with larches (*Larix*), coastal grassland with scattered alders (*Alnus*) or dwarf pines (*Pinus*) or willow (*Salix*) thickets, or edges of birch (*Betula*) woods; in S of range also in steppe-like habitats (especially along river valleys). Found also in tropical forest and edge in China (race *lucionensis*). In S Ussuriland, *confusus* prefers unwooded areas around lower rivers in coastal plain, and occurs also along upper rivers. Race *superciliosus* breeds mostly in grassland with scattered deutzia shrubs (*Deutzia*), or coastal thin oak (*Quercus*) woods, or farmland with hedges; in Japan, found only in open land on Hokkaido, where exhibits rather strict habitat preferences, but in C Honshu breeds also in residential area, using shrubs (e.g. *Vitis coignetiae*, *Malus baccata* etc.) for nesting. Breeds from sea-level to low mountains, to 1800 m in Altai region of S Siberia; to c. 450–650 m in Kamchatka; in Japan, to 1400 m in C Honshu but mainly in coastal areas on Hokkaido. In non-breeding quarters occurs in open lowlands with cultivations, forest edge, clearings, scrubland, grassy hillsides with scattered bushes and small trees.

Food and Feeding. Diet mainly insects, also other arthropods and small vertebrates. Orthoptera and beetles (Coleoptera) usually main prey; vertebrates taken are mostly small mammals, lizards, amphibians, and small passerine birds (including nestlings). On Sakhalin I, stomachs contents of ten individuals revealed remnants of Orthoptera, various beetles i.e. *Pterostichus* (ten items), *Dytiscus*, *Silpha perforata* (three), *Phosfuga atrata*, *Xylodrepa sexcarinata* (six), *Necrophorus*, a curculionid, and *Geotrupes laevistriatus*, also three bumblebees (*Bombus*), three wasps (*Vespa*), a lacerid lizard, and a frog; pellets contained the weevil *Byssopogon sachalinensis* (nine), a *Vespa* wasp, ants (Formicidae), Lepidoptera larvae, and a lizard. Items delivered to nestlings included spiders (Araneae), insects, vole and lizard; in another nest, main prey items delivered were spiders (36.8%), beetles (27%), and adult and larval Lepidoptera (13.9%). In S Ussuriland, main prey during summer were large grasshoppers, but adults also hunted frogs and nestlings of Chestnut-eared Bunting (*Emberiza fucata*). On Hokkaido (race *superciliosus*), arthropods constituted 99% of prey delivered to nestlings (Lepidoptera larvae 33.1%, Orthoptera 24.1%, Arachnoidea 20.5%); food remnants in nests consisted of beetles (*Silpha*, Scarabaeidae, Harpalidae, Elateridae, Carabidae including *Carabus conciliator*), also *Vespa pacifica*, and bumblebees; impaled prey of a pair in breeding season were scarabeid beetles (of genus *Anomala*), Hymenoptera, and *Locusta migratoria*; adult seen to take juvenile Black-faced Bunting (*Emberiza spodocephala*). Uses low hunting perches, 1–3 m (mostly below 2 m) high, from which swoops or sallies for prey; most prey caught on ground. Regularly caches food.

Breeding. Laying from Jun in Siberia and S Ussuriland, from end May on Sakhalin and in Amurland, and from May in E China; in Japan laying from late May to Jun; single brood. Nest built by both sexes, mostly by female, work taking less than one week, an open cup made from twigs, grass stalks, rootlets, dry leaves and moss, lined with hair and fine grass, in S Ussuriland outer wall chiefly of bark fibres and inner part of thin dry grasses, outer diameter 11.5–13 cm, height c. 10.5–12 cm, internal diameter 6.5–8 cm and depth 4.5 cm; placed 6–9 m (exceptionally, to 18 m) above ground in tree or tall bush, but in N & E of range (nominate race and *confusus*) usually lower, below 3 m, sometimes even on ground in grass or among leaves, e.g. nest of *confusus* at base of solitary shrub in grassland. Clutch 3–8 eggs, usually 4–6, from reddish-white with fine reddish-brown spots to greenish or buffish with brown, grey and/or purple spots; replacement clutch laid if first attempt failed during laying or incubation stages; incubation by female, fed on nest by male, period 12–16 days, mostly 12–14 days (mean 12.8 days on Hokkaido); chicks fed by both parents, nestling period 13–16 days, mostly 14–15 days; young remain near nest for minimum of 2 weeks after fledging. Nests parasitized by Common Cuckoo (*Cuculus canorus*), Indian Cuckoo (*Cuculus micropterus*) and Horsfield's Cuckoo (*Cuculus horsfieldi*); e.g. 5% of pairs on Hokkaido thus parasitized. On Hokkaido, mean hatching success 87.8–100%, and of 19 failed nests twelve (63%) were preyed on and seven (37%) were deserted; nesting success decreased annually, from 75% in 1992 to 56% in 1993, 55% in 1994, 50% in 1995 and 29% in 1996.

Movements. Nominate race, *confusus* and *superciliosus* migratory; *lucionensis* partially migratory. Migration routes poorly known, but non-breeding grounds situated in C & S parts of Indian Subcontinent E to Myanmar and Malay Peninsula (nominate race), extending S to Sundas; race *confusus* seems to spend non-breeding season in S Peninsular Malaysia and Sumatra, and *superciliosus* migrates to S China, Hainan, SE Asia (mainly Indochina), Sumatra, Java and W Lesser Sundas. Race *lucionensis* apparently resident in S Korea and probably E China, but most of population migrates to non-breeding grounds in coastal SE China, Taiwan, Philippines, Borneo, Sulawesi (mostly N), less frequently Moluccas (vagrant Halmahera and Seram).

Status and Conservation. Not globally threatened. Few data on population levels. Possibly fairly common in much of range; uncommon to rare in Japan. No information on current status of nominate race and *confusus*. In Japan, race *superciliosus* has declined drastically, and may even be in danger of extinction: on Hokkaido, populations of this race declined by c. 80% during period between 1973–74 and 1990, also decreased by 67% over the four years 1993–1996 at one site (Ishikari), declined by 86% near Sapporo and by 50% in C Hokkaido, and became extinct at two sites; in C Honshu, population on Nobeyama plateau was between 50 and 60 pairs, but declined to

20 individuals in 1998, and then remained stable at fewer than ten individuals, but in 2005 no pair bred, and at other sites (Akita, Miyagi, Gunma, Tokyo, Tochigi, Yamanashi, and Shizuoka) numbers gradually declined over c. 10 to 30 years since late 20th century. Status of race *lucionensis* in Japan uncertain; local on Kyushu, and apparently bred in Daito Is (Kita-daito and Minami-daito) in the past, but shrike population on those islands from middle 1970s to late 1980s identified as *L. bucephalus*; further research required on current breeding distribution of *lucionensis* in Sea of Japan and elsewhere. Known to occur in several protected areas in non-breeding range, from Kaziranga and Nagarhole National Parks, in India, E to Cat Tien National Park, in Vietnam.

6. Burmese Shrike

Lanius collurioides

French: Pie-grêchée à dos marron **German:** Burmawürger **Spanish:** Alcaudón Birmano
Other common names: Myanmar/Chestnut-backed/Chestnut-rumped Shrike

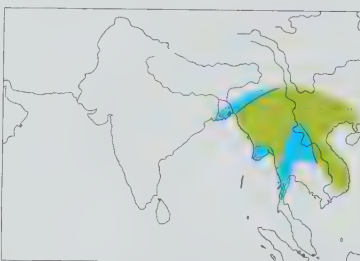

Taxonomy. *Lanius collurioides* Lesson, 1831, Pegu, Myanmar.

Sometimes thought to form a superspecies with *L. vittatus*, the two being separated geographically by R Brahmaputra. Two subspecies recognized.

Subspecies and Distribution.

L. c. collurioides Lesson, 1831 – breeds Myanmar (S to C Tenasserim), S China (W & C Yunnan E to S Guizhou and SW Guangdong), NW & W Thailand, Laos, E Cambodia and N Vietnam.

L. c. nigricapillus Delacour, 1926 – SC & S Vietnam (S from Da Lat Plateau).

Descriptive notes. 19–21 cm; one immature female 26 g. A medium-sized shrike with long slender tail. Male nominate race has black forehead and facial mask, slaty-grey crown and nape to upper mantle; rest of upperparts, including rump and uppertail coverts, plain rufous-chestnut; upperwing dark brown, wing-coverts, tertiaries and secondaries with chestnut-buff fringes, clear white patch at base of primaries; tail black, outer feathers white; throat white, underparts white with faint buff wash, undertail white with black feather tips; iris dark reddish-brown; bill grey-brown with dark tip; legs greyish-black. Female is similar

to male but slightly duller and paler, with lores and nasal feathers striped with white to buff; some barring may be present on breast. Juvenile is like female, but mask brown with some buffy streaks, crown to upper mantle greyish-brown with black barring, upperparts warm buffish with black subterminal bars, upperwing darker brown with pale fringes and no or small white primary patch, tail brown with paler outer retrices, undertail dull white, underparts dirty white with buff wash, heavily vermiculated on breast and flanks; immature very like female but with barring on upperparts. Race *nigricapillus* is darker than nominate, male with blackish-slate crown and nape and darker chestnut upperparts, female less different from male (than in nominate) but with slightly paler hindcrown and nape and duller chestnut upperparts. **VOICE.** Song quiet, variable, starts hesitantly but becoming a musical series of rapid and scratchy rattles, squeaks and trills. Call a harsh single "jao"; alarm a loud, rapid chatter, "chikachikachitit", "chekochekochechitititit" or "cheteteter". **Habitat.** Clearings and edges of secondary broadleaf forest and pine (*Pinus*) forest, scrubby open woodland, cultivation, roadside vegetation and gardens; in non-breeding season widespread in cultivated lowland areas. Occurs from sea-level to 2500 m; in SE Asia mainly 600–1830 m, in S Vietnam to 2400 m and in S China to 2500 m.

Food and Feeding. Feeds primarily on insects, including especially Orthoptera; also lizards and other small terrestrial vertebrates. Found singly and in small parties; when in parties very noisy and active, with wing-flapping and screeches while squatting on bushes; this behaviour possibly connected with pair formation. Often confiding and easy to approach. Hunts in typical shrike fashion from exposed vantage point, e.g. top of bush or tree or on telegraph wire, from which it dives down to take prey on ground; also uses more shaded perches, and hops on ground when seeking prey.

Breeding. Season Mar–Jun; laying mostly Apr–May in Myanmar, recorded in Jun in S China (possibly referring to second brood); probably two broods per year. Probably monogamous and territorial. Nest an open cup, size varying greatly, made from leaves, grasses, feathers and lichens, covered with spider webs, lined with fine grasses, built 1.5–3.5 m above ground and usually in thorny bush, sometimes in tall thin bush, small sapling or fir tree (*Abies*). Clutch 3–6 eggs, generally 5, variable in colour, mostly pale greenish-white but sometimes yellowish-white, and with pale purplish and yellow-brown spots chiefly at large end; no information on incubation and nestling periods.

Movements. Resident and migratory populations. Much overlap in breeding and non-breeding ranges, but in winter extends more to S & W and probably also SE; widespread in some lowland areas in winter. In NE India, migrant or winter visitor in S Assam hills and Manipur in Oct and Feb–Apr; reported also in SE Bangladesh (Chittagong region), but apparently rare. In Myanmar migration starts in Jun, when young and adults observed in C, SW & S plains, probably as far S as Tenasserim; returns to breeding areas in N from Mar onwards; some irrigated areas only temporarily vacated (from Mar to Jun). In Thailand resident in NW & W areas; non-breeding visitor in N & E plains, but absent in C & SE regions. Chinese populations apparently resident, with some altitudinal movements: same probably applies to Indochina populations S to S Vietnam, including those in Laos and Cambodia. Vagrant in Hong Kong (Mar).

Status and Conservation. Not globally threatened. Generally not uncommon; quantitative data on population levels lacking. Locally fairly common to common in Myanmar, Thailand, Cambodia, Laos and Vietnam; uncommon in S Chinese provinces of Yunnan, Guizhou, Guangxi and Guangdong. In NE India, scarce passage migrant and non-breeding visitor in S Assam hills but commoner in Manipur; breeding status in this region uncertain, nest reported in N Cachar (Assam) in late 19th century but no breeding reports since then.

Bibliography. Ali & Ripley (1987), Chen Fuguan *et al.* (1998), Échécopar & Hùe (1983), Grimmett *et al.* (1998), Harris & Franklin (2000), Kazmierczak (2000), Lefranc & Worfolk (1997), MacKinnon & Philipps (2000), Rasmussen & Anderton (2005b), Ripley & Bechler (1990), Robson (2000b), Smythies (1986).

7. Emin's Shrike

Lanius gubernator

French: Pie-grièche à dos roux **German:** Rotbürlwürger **Spanish:** Alcaudón de Emin
Other common names: Emin's Red-backed Shrike

Taxonomy. *Lanius gubernator* Hartlaub, 1882, Central Africa = Langomeri, Uganda.

May form a superspecies with *L. souzae*. Monotypic.

Distribution. S Mali (R Niger) and N Ivory Coast E discontinuously to S Sudan, NE DR Congo and N Uganda.

Descriptive notes. 14–16 cm; 23.5 g. The smallest *Lanius* shrike. Male has black facial mask extending narrowly over base of bill, bordered above by thin whitish supercilium; crown to hindneck and upper mantle pale grey, merging into bright chestnut of mantle, back, scapulars, rump and uppertail-coverts; upperwing dark brown, greater wing-coverts, secondaries and tertials with broad chestnut edges, white patch at base of primaries; tail dark brown with light rufous wash, white outer feathers; white below, lower breast, belly and flanks washed pale rufous to reddish-buff (more intensively on flanks); iris dark brown;

bill black; legs greyish-black. Differs from very similar *L. collurio* in smaller size, rufous (not grey) rump, rufous-buff (not pinkish) underparts and more contrasting white throat, presence of white wing patch. Female is duller than male, black areas of male more brownish, grey extending farther on to mantle; differs from *L. collurio* female in uniformly coloured (unbarred) underparts. Juvenile has dark brown facial mask, grey-brown crown, neck and upperparts with black barring, white throat, whitish with black crescents below but tawny on flanks and breast. **VOICE.** Song consists of a short and rapid series of a few simple varied whistles, e.g. “tweet-u-wee-u-weet” and “trip-tu-trip-srtp”, mixed with low hoarse “chweehh” notes. Calls include low hissing note and a loud clear note; also various twitterings, whistles and a low harsh “zut zut”, “chuz-zoo-wit” and “chark chark”. Apparently often quiet, as seen frequently but no call heard.

Habitat. Little studied. Grassland savanna with bushes, grass-covered open woodland and forest clearings; also in degraded soudanian-guinean savanna, gallery forest, also abandoned cultivated fields and villages in open bushy grassland with woodland. At 150–1500 m.

Food and Feeding. Insectivorous. Stomach contents included beetles (Coleoptera), mantises (Mantodea) and small Orthoptera. Solitary or in small groups of 4–5 individuals; occasionally joins mixed feeding parties. Perches openly on top of bush, fence or telephone wire; takes most food from ground, but observed also to make aerial captures and to search in middle and upper levels of woodland.

Breeding. Starts in Mar–Apr (at beginning of rains) in DR Congo, where juveniles seen in Jul; possible breeding also Mar–Apr in Sudan; female with incubation patch in Mar and courtship feeding observed in Apr in Ivory Coast; adults with recently fledged juveniles in mid-Jun in Nigeria. Described as monogamous, but possible co-operative breeding suspected. No other information.

Movements. Little known. Apparently resident, with no evidence of regular movements. A few observations, however, suggest at least occasional wanderings, e.g. all Mali records in Aug–Nov.

Status and Conservation. Not globally threatened. Little information available. Generally uncommon to rare; global population estimated at fewer than 70,000. Range not small, estimated 130,000 km², but presence very localized. Recorded in nine countries; rare in Mali (Niger R), where may be only non-breeding visitor; uncommon in Ivory Coast (two localities), rare in N Ghana and rare in Nigeria (7–8 localities), rare or uncommon in NC Cameroon, uncommon in Central African Republic and S Sudan, uncommon to locally frequent in NE DR Congo, and uncommon and local in N Uganda. Probably present but overlooked in Burkina Faso, Togo and Benin. Present in several protected areas: recorded in Comoé and Mont Sangbé National Parks, in Ivory Coast; regular in Kainji National Park and recorded in Yankari National Park, in Nigeria; uncommon in Manovo-Gounda-Saint Floris National Park, in Central African Republic; present in Garamba National Park, in DR Congo; and present in Kipedo Valley and Murchison Falls National Parks, in Uganda.

Bibliography. Borrow & Demey (2001), Chapin (1954), Demey & Fishpool (2008), Fishpool & Evans (2001), Fry *et al.* (2000), Hall & Moreau (1970), Harris, T. (1998), Harris, T. & Franklin (2000), Lefranc & Worfolk (1997), Salewski (2001), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002).

8. Souza's Shrike

Lanius souzae

French: Pie-grièche de Souza **German:** Rostmantelwürger **Spanish:** Alcaudón de Souza

Taxonomy. *Lanius souzae* Bocage, 1878, Caconda, Angola.

May form a superspecies with *L. gubernator*. Three subspecies recognized.

Subspecies and Distribution.

L. s. souzae Bocage, 1878 – S PR Congo, SW DR Congo and Angola (excluding W & S).

L. s. burigi Chapin, 1950 – Rwanda, Burundi and W Tanzania.

L. s. tacitus Clancey, 1970 – SE Angola (Cuando Cubango) E to SE DR Congo (Katanga), Zambia, Malawi, W Mozambique, extreme N Zimbabwe and NE Namibia, probably also in N Namibia (Okavango) and N Botswana (R Chobe).

Descriptive notes. 17–18 cm; 21–30 g. Smallish shrike with barred upperparts and long slender tail. Male nominate race has black facial mask from bill base through eye to rear of ear-coverts, whitish supercilium; crown, nape and mantle pale grey, scapulars white, back rufous-brown, finely barred black, rump as back but less barred and generally greyer; flight-feathers dull brown, tertials and upperwing-coverts rufous-brown and finely barred black; tail dull brown with thin rufous-brown and black bars, all except central pair of feathers tipped white, outermost pair with much white; throat white, underparts creamy

to whitish-buff, occasionally with faint barring; iris dark brown; bill black, pale base of lower mandible; legs dark grey. Distinguished from similar *L. collurio* mainly by duller coloration, with grey upperparts becoming browner on lower back, both narrowly barred blackish. Female is similar to male but slightly duller, with distinctly tawny flanks. Juvenile has mask brown, crown and upperparts rufous-brown with narrow blackish barring, whitish scapulars barred dark, whitish underparts densely vermiculated with dark brown. Races differ mainly in size and in colour of upperparts and flanks: *burigi* is smaller than nominate, has back more brownish-grey, less russet-brown, without dusky vermiculations on lower back to uppertail-coverts, wings and tail darker, much less rufous, and less barred blackish, female has larger and distinctly deeper rufous area on lower flanks; *tacitus* also is smaller than nominate, has mantle drab or dull olive-brown, wings paler, female has smaller, paler and duller rusty wash on flanks. **VOICE.** Quiet; various chattering and whistling sounds, rarely heard. Territorial call probably a muted “tzzeeee” whistle; contact call “tzzz” or “ziz”; alarm a discordant “tzz-jert” and quiet “tzzz”; low “tzzzzick” by wary individual near/on nest, also a low grating chirp and low chattering uttered at intervals by female while human observer examined nest.

Habitat. Woodland, mainly in areas where forest thins out, also edges of wooded gardens. In most of range strongly associated with light miombo (*Brachystegia*) woodland with patches of short grass, but occurs also in mixed broadleaf and more open savanna; seems to be strictly associated with *Pericopsis* savanna in Rwanda, and occurs in both miombo woodland and *Burkea* savanna in Zambia. Few data on elevational range; occurs at 1000–1800 m in Malawi.

Food and Feeding. Few data. Recorded food arthropods, i.e. insects and large spiders (Araneae); possible that vertebrates occasionally taken. When hunting, usually perches in middle stratum below forest canopy, scanning the ground for prey. Small items usually consumed immediately; larger ones carried back to a perch before being eaten.

Breeding. Season at least Sept in Angola, Sept–Nov in DR Congo and Zambia, and Sept–Dec (mainly Oct) in Malawi. Possible co-operative breeding has been suggested on basis of apparent prevalence of small groups during breeding period. Nest can take up to 3 weeks to build, a small open cup made from leaf petioles, twigs and grasses, bound together with spider web, lined with fine roots, tendrils and grasses, exterior often decorated with fluffy seedheads or lichens, generally well camouflaged, placed usually c. 5 m from ground in fork or on horizontal branch of trees (e.g. *Brachystegia* or *Uapaca*), sometimes on lichen-covered branch or in bare tree. Clutch 1–4 eggs, usually 3, pale buffish or greenish-grey with brown, grey and purple freckles around larger end; incubation apparently by female alone, fed away from nest by male; no information on duration of incubation and nestling periods.

Movements. Mainly resident, but information scarce. Possibly some local movements in dry season; records in S of range could involve individuals originating from farther N. Believed to be migratory in Malawi, as it is absent in certain areas outside breeding period.

Status and Conservation. Not globally threatened. Generally uncommon. Has large range, with estimated global extent of occurrence of 1,700,000 km², but within this it is sparsely distributed and local. Little information available on any changes in distribution or abundance, but thought not to be at any immediate risk. As an African species associated with forest-savanna ecotone and other woodland habitats, it probably merits conservation research priority. Occurs in several protected areas, e.g. Dzalanyama Forest Reserve, in Malawi.

Bibliography. Benson (1950), Borrow & Demey (2001), Chapin (1954), Clancey (1970a), Dean (2000), Dowsett *et al.* (2008), Eck (1975), Hall & Moreau (1970), Harris & Arnott (1988), Harris & Franklin (2000), Harrison *et al.* (1997), Hockey *et al.* (2005), Immelmann (1968), Lefranc & Worfolk (1997), Olivier (1944), Schwind (1968).

PLATE 58

Family LANIIDAE (SHRIKES) SPECIES ACCOUNTS

9. Bay-backed Shrike

Lanius vittatus

French: Pie-grièche à bandeau German: Rotschulterwürger Spanish: Alcaudón Dorsicastaño

Taxonomy. *Lanius vittatus* Valenciennes, 1826, Pondicherry, India. Sometimes thought to form a superspecies with *L. collurioides*, the two being separated geographically by R Brahmaputra. Other studies suggest close relationship either with *L. collurio* on basis of coloration or with *L. cristatus*; also resembles *L. minor* in territorial flight display and *L. schach* in vocalizations. Races intergrade in E Pakistan (NW Punjab and Sind). Two subspecies recognized.

Subspecies and Distribution.

L. v. nargianus Vaurie, 1955 – breeds SE Turkmenistan, SE Iran (Hormuzgan, Sistan and Baluchistan, probably also Khorasan), Afghanistan and Pakistan (Baluchistan E to Sind and Punjab).

L. v. vittatus Valenciennes, 1826 – S & E Pakistan, Kashmir, India (except N & NE) and S Nepal.

Descriptive notes. 17–19 cm; 18–26 g. A comparatively small shrike with relatively long and graduated tail. Nominant race has black forehead and facial mask, pale grey crown and nape, dark grey upper mantle merging into chestnut-maroon mantle, back and scapulars; rump and uppertail-

coverts greyish-white; upperwing black, conspicuous white primary patch, tail black, outermost pair of rectrices mostly white; chin and throat whitish, underparts whitish with buff-brown to rufous-brown wash, flanks deeper rusty-coloured; iris dark brown; bill and legs black. Sexes alike; some females identifiable by narrower frontal band. Juvenile has facial mask brown and less extensive, is greyish-brown above, crown and mantle barred black and buff, wing-coverts and tertials edged buff, no white wing patch, tail rufous-brown, underparts dull white to pale brown with dark barring, mainly on breast and flanks; immature

between juvenile and adult, with greyish-brown head and mantle, but back, wings (including white wing patch), tail and underparts more adult-like, although some feathers may still be barred. Race *nargianus* is larger than nominant, with longer bill and wing, and with paler, less brightly coloured upperparts, female often identifiable by duller plumage although this race more individu-

ally variable than nominate. VOICE. Song a pleasant, rambling warble intermixed with harsh notes and much mimicry. Call a harsh churring “chur-r” or “chee-urr” or “keechuw”; alarm a rapid chatter, “tzzrr”, “krrrr-krrrr”, “trrrr-trrrr” or “cha-a-a-a”.

Habitat. Variety of open, dry bushy areas with scattered trees, also cultivated areas and edge of more wooded areas. Preferred habitat intermediate between dry semi-desert (favoured by local race *lahtora* of *L. meridionalis*) and more wooded, watered areas (favoured by *L. schach*). In N & W or range found in semi-desert and dry rocky areas with bushes and some trees, in pistachio (*Pistacia*) woods, in cultivated areas in plains, valleys, foothills and slopes; in Iran in dry riverbeds, plains and slopes with acacia (*Acacia*), *Prosopis* and *Ziziphus* trees. In Turkmenistan almost entirely at 600–800 m in hilly, south-facing pistachio woodland with *Pistacia vera*. S populations breed in diverse habitats, from e.g. open scrub and thorny tree jungle to grazing land and cultivated areas around villages, gardens, parks and, especially in Indus Valley, in tree plantations along canal banks; avoids desert landscape of Thar. Non-breeding habitat similar, with preference for scrub with agricultural cropland (rather than solely scrub or cropland). Occurs from sea-level to 2000 m, but in Nepal observed at 2600 m, 2810 m and 3965 m; vagrant in Bhutan at 3760 m.

Food and Feeding. Almost exclusively insects, mainly beetles (Coleoptera) and Orthoptera, also Lepidoptera, Neuroptera, flies (Diptera) and Hymenoptera; lizards and occasionally mice (Muridae) and nestling birds observed as prey. In Turkmenistan 90% of items brought to nestlings were Orthoptera. Solitary or in pairs; conspicuous and relatively tame. Typical shrike hunting behaviour: watches from exposed perch, preferably bush or electric wire, usually 2–2.5 m above ground, diving down to catch food on ground within radius of 10 m. Stores prey in caches.

Breeding. Season May–Jul in Turkmenistan, Mar–Aug in Pakistan, and in India Apr–Jul in NW, Feb–Sept in C and in Feb–Apr in S; usually two broods per year, seldom three. Monogamous, and at all seasons highly territorial. Solitary nester, inter-nest distance mostly 150–200 m or more, but pairs sometimes less than 50 m from each other in very favourable habitats. Nest a quite small and neat cup, diameter c. 10.5 cm and height c. 7 cm, built from grass, feathers, wool and fibres, often with lichens on outside, lined with grass and other soft material, placed 0.9–10 m (mostly 1.5–4 m) above ground in fork or crotch of thornbush or small tree, wide variety of trees used, but thorn trees such as *Acacia* locally favoured, and in Turkmenistan only pistachio trees selected; territory size appears to be 1–2 ha. Clutch 3–5 eggs, usually 4, often whitish or pink-white to green-white with brown spots and blotches; incubation mostly by female, fed on or near nest by male, period 14–15 days; male supplies most food, passes this to female and she feeds young, nestling period 14–15 days.

Movements. Resident and migratory. Race *nargianus* mainly migratory, but little information about populations in extreme W of range. In Iran appears to be absent in Jan, when none found during surveys since year 2000 in S & SE; in S Turkmenistan leaves breeding areas Aug–Sept, migrating to India, returns end Apr. In Pakistan, birds from higher elevations in Baluchistan leave breeding grounds in Oct, return end Mar. Nominate race mostly resident, but with some marked seasonal movements, particularly in N parts. Rare non-breeding visitor to United Arab Emirates (Sept–Apr). Vagrant Saudi Arabia (Apr), Oman (Apr, May, Oct), Bhutan, Bangladesh and Sri Lanka.

Status and Conservation. Not globally threatened. Generally common in India and Pakistan; sparse information from Iran but at least locally common, e.g. in Genu Protected Area and near Chabahar; local in Turkmenistan, where known from Badchyzskij and Kushka areas; very local in Afghanistan but little information, recorded Lashkar Gah, Kandahar, Punjab and Kabul. Densities range from 25–30 pairs/km² in N India to 12–14 pairs/km² in S Turkmenistan. Although present in many protected areas, core habitat consists of cultivated areas, which are not protected.

Bibliography. 10. Long-tailed Shrike *Lanius schach*

French: Pie-grièche schach **German:** Schachwürger **Spanish:** Alcaudón Schach
Other common names: Black-headed/Black-capped/Schach Shrike, Rufous-backed/Red-backed(1)/ (Southern) Rufous-rumped Shrike; Large-nosed Shrike (*nasutus*); Dusky Shrike (melanistic variant “*fuscatus*”)

Taxonomy. *Lanius schach* Linnaeus, 1758, “Canton area”, Guangdong, south-east China. Closely allied with *L. tephronotus*, and formerly treated as conspecific, but differs in morphology; moreover, the two are largely sympatric and, although race *lahulensis* of *L. tephronotus* sometimes considered to represent a hybrid population between them, no definite proof of interbreeding. Mainland races tend to intergrade; intermediates between *erythronotus* and *tricolor* described as *nigriceps*. Other proposed races are *formosae* (described from Taiwan) and *hainanus* (from Hainan I), but both are considered inseparable from nominate; name *fuscatus*, given to melanistic birds from SE China and Hainan, has no taxonomic significance. Nine subspecies currently recognized.

Subspecies and Distribution.

L. s. erythronotus (Vigors, 1831) – breeds SE Kazakhstan, S Uzbekistan, Kyrgyzstan, S Turkmenistan, Tajikistan, Afghanistan and Pakistan (except SW) E to N & NC India; probably also NE Iran.

L. s. caniceps Blyth, 1846 – NC & peninsular India and N Sri Lanka.

L. s. tricolor Hodgson, 1837 – Nepal and E India E to Myanmar, S China (S Xizang, Yunnan), N Laos and N Thailand.

L. s. schach Linnaeus, 1758 – C, S & SE China (including Hainan), Taiwan and N Vietnam (Tonkin and Annam).

L. s. longicaudatus Ogilvie-Grant, 1902 – C, SE & S Thailand and S Laos, possibly also S Myanmar (Tenasserim).

L. s. bentel Horsfield, 1821 – S Malay Peninsula, Sumatra, Java, SE Borneo and Lesser Sunda Is (E to Timor).

L. s. nasutus Scopoli, 1786 – Philippines (except Palawan and Sulu Is).

L. s. suluensis (Mearns, 1905) – Sulu Archipelago (Jolo), in S Philippines.

L. s. stresemanni Mertens, 1923 – E New Guinea (Huon Peninsula and adjacent hinterland, S slopes of mountains in SE).

Descriptive notes. 20–25 cm; 50–53 g (nominate), 33–42 g (*erythronotus*). Medium-sized shrike with long to very long, graduated tail. Nominate race has forehead and facial mask (extending as broad band through lores and eye to lower nape side) black, crown to mantle dark grey, back and rump rufous; upperwing blackish, tertials edged pale buffish-white, secondaries narrowly tipped pale, conspicuous white patch at base of primaries; tail black, tipped white, outer rectrices edged

absent), blackish tail feathers with buffy tips, throat white, underparts whitish with rufous-buff wash and variably vermiculated dark. Races differ mainly in size (nominate largest), tail length, and colour of head and upperparts: *erythronotus* is similar to nominate but distinctly smaller, somewhat duller, and with narrower black band on forehead; *caniceps* is paler, with less rufous on upperparts; *tricolor* has complete black cap, small greyish area on upper mantle, rest of upperparts deep rufous; *longicaudatus* is similar to previous but tail much longer (longest of all races), upperparts darker rufous, primary patch larger; *bentel* has tail almost as long as last, amount of black on head variable, upperparts similar to *caniceps*, primary patch very variable, but normally small or lacking; *nasutus* is like *tricolor* but mantle all grey, back paler rufous; *suluensis* is very similar to previous but somewhat paler above, mantle whitish-grey; *stresemanni* also is similar, but darker rufous above, with less extensive grey on mantle. VOICE. Calls harsh, squealing or yapping, described as “scha-scha-scha-schi, schi, schi” and “scha, schach-schach” (race *nasutus*) and “ketch-ketsch...” or “tchert...”; also a disyllabic “tch-ick”, “cha-dit” or “kerr-ick” (nominate race), and repeated “ger-lek” or “jülek” (*erythronotus*). Race *stresemanni* extends call to a yapping “yaou-yaou” or “choo-wee”, *nasutus* to a repeated “keoo-keoo”. Some notes described as reminiscent of Common Quail (*Coturnix coturnix*). Also a great variety of harsh buzzy and rustling sounds, including alarm “kerr-kerr...”, “zerr-zerr...” and similar; *nasutus* and *bentel* recorded as uttering intense “keek-keek-keek...” chatter. Song, lasting for up to 15 minutes, includes melodious warbles and whistles, similar to those of *Acrocephalus* warblers, and may incorporate songs of other bird species.

Habitat. Open country with scrub, light woodland and bushes, mainly in cultivated areas, also steppe and semi-desert, grassland with scattered bushes, young plantations, gardens, parks, occasionally edges of evergreen forest. In C Asia, commonly by cultivation with planted trees, such as shelter-belts along roads and railways, avenues and parks in towns, and orchards in villages. In Sri Lanka, breeds in scrub-jungle near coast; in Thailand in paddyfields; in Sumatra found in reedbeds bordering cultivation. Requires presence of suitable perches, shade and accessible food. Mainly in lowlands, but up to limits of deciduous tree cover in mountains; nominate race typically to 1500–1700 m, but in valleys of small tree-fringed rivers to c. 3050 m; *tricolor* reaches 3000 m and occasionally 4300 m in Himalayas; in New Guinea, *stresemanni* widespread only in mountain areas at 1100–2600 m.

Food and Feeding. Very opportunistic. Wide variety of insects, with preference mostly for larger species and groups, e.g. grasshoppers and crickets (Orthoptera) and beetles (Coleoptera); also, regularly takes vertebrates such as small mammals, lizards, frogs, crabs and small birds, including nestlings up to size of Laughing Dove (*Streptopelia senegalensis*). Comparatively bold and fearless. Hunts from prominent perch; takes most of its prey on ground, but also hawks insects in air; hops on ground. Occasionally steals food from other birds. Impales some of its victims.

Breeding. Laying from end Mar to Jul, mainly from Apr/May, in N & C parts of range; in S laying recorded in Feb, Jun–Sept and Dec in Malay Peninsula, in all months (peak May–Aug) in Java, and Jun–Nov in New Guinea; locally double-brooded (lower elevations in Afghanistan, Pakistan and India). Monogamous. Nests often in loose groups, e.g. up to 6–7 pairs/8 ha in green urban area of Kabul (Afghanistan) and 26 pairs in 7 ha in Turkmenistan. Nest built by both sexes (race *erythronotus*), a generally rather bulky open cup made from grasses, thorny twigs, moss, roots and leaves, often man-made materials incorporated, lined with finer grasses and the like, placed in thorny bush or in tree, locally in reeds or tall grass, at variable height, usually 3–5 m (sometimes down to 1.5 m, exceptionally up to 24 m) in most of range, often at 4–12 m in tall tree in urban sites; in N Philippines at 0.75–3 m, and in Malay Peninsula at 0.9–3.5 m in bushy vegetation among creepers or ferns. Clutch 2–6 eggs, mostly 4–6, apparently varying geographically, occasionally up to 8 in C Asia, and normally 4 in Sri Lanka, 3 in Malay Peninsula and 2 in New Guinea; whitish to pale olive, with reddish-brown speckles on underlying greyish spots, markings often in band around broad end; replacement clutches frequent if earlier ones lost; incubation by female, period 13–16 days; nestling period 14–17 days; juveniles remain in natal territory for up to 2 months. Nests regularly parasitized by cuckoos, in India including Common Cuckoo (*Cuculus canorus*), Common Hawk-cuckoo (*Cuculus varius*) and Jacobin Cuckoo (*Clamator jacobinus*).

Movements. Resident, partially migratory and migratory; some altitudinal movement also occurs. Non-breeding range lies entirely within breeding range. In NW part of range (C Asia) race *erythronotus* migratory, wintering Oct–Mar in Indian plains; in Himalayas, *tricolor* often winters within breeding range, but generally in foothills below 1700 m; *caniceps* in S India appears to make only local seasonal movements. In China, nominate race resident or partial migrant in N territories. Populations in S & E of range mainly, if not entirely, sedentary. Several sight records and two specimen records from NE Borneo probably refer to vagrant *nasutus*. Vagrants of race *erythronotus* recorded W to Middle East, Sweden and Britain.

Status and Conservation. Not globally threatened. Locally common to uncommon; rare in extreme NW of range, and possibly extinct in e.g. Tajikistan. Has large global range, with extent of occurrence estimated in range 1,000,000–10,000,000 km². General decline in W of range offset by increase in E. Protected in most countries; in some listed as “endangered”. A decrease in use of agricultural pesticides, combined with effective conservation of semi-open habitats (pastures, meadows) with traditional farming and old orchards, would probably be the most effective measure to ensure this species’ future survival.

11. Grey-backed Shrike

Lanius tephronotus

French: Pie-grièche du Tibet

German: Tibetwürger

Spanish: Alcaudón Tibetano

Other common names: Tibetan Shrike

Taxonomy. *Collurio tephronotus* Vigors, 1831, Himalayas = near Darjeeling, India.Closely allied with *L. schach*, and formerly treated as conspecific, but differs in morphology; moreover, the two species are largely sympatric and, although race *lahulensis* sometimes considered to represent a hybrid population between them, no definite proof of interbreeding. Two subspecies recognized.**Subspecies and Distribution.***L. t. lahulensis* Koelz, 1950 – breeds N Kashmir E to CN India (Uttaranchal Pradesh), and probably SW China (W Xizang).*L. t. tephronotus* (Vigors, 1831) – breeds Nepal E to NE India (Arunachal Pradesh), and C & S China (S Gansu, Ningxia and E Shaanxi S to SE Qinghai, S & E Xizang, SE Yunnan and C Guizhou); non-breeding also S to Bangladesh, Myanmar, Thailand and Indochina.**Descriptive notes.** 21–23 cm; 39–54 g. Rather small shrike with long tail. Nominant race has black lowermost forehead (just over base of bill) and facial mask through lores and eye to rear ear-coverts; crown to nape and most of upperparts dark grey, small rufous rump patch; upperwing black, most wing-coverts, secondaries and tertials fringed pale rufous to whitish, sometimes tiny white patch at base of primaries (often lacking); tail chestnut-brown, tipped buffish, outermost pair of rectrices light brown; throat and underparts white, breast side and flanks rufous, undertail brownish-grey; iris dark brown; bill black; legs dull black. Sexesvery similar. Juvenile is browner above than adult, with less marked brown (not black) facial mask, horn-coloured lower mandible, has crown finely barred, upperparts and much of underparts heavily barred dark brownish. Race *lahulensis* is smaller and weaker-billed than nominate, also much paler, brownish-grey above, with rufous lower back and rump, white primary patch usually slightly larger and more visible, tail sometimes blackish (not brown). **Voice.** Little known. Territorial call described as harsh “zzert-zzert...”, “tchert-tchert...” or “tzt-zt-zt...”; repertoire includes also a repeated “ktcht-ktcht-ktcht” given at dusk or as alarm. Breeding song subdued and musical, with mimicry of other bird calls lasting several minutes. Voice seems to be similar to that of *L. schach*. **Habitat.** Breeds at high elevations in forest clearings, plateau plains and mountain meadows dotted with small trees or fairly large bushes; to at least 4500 m in Nepal (becoming common from 2700 m upwards) and in S China (Yunnan). Post-breeding habitat in Sichuan (C China) either young open coniferous stands with forest clearings dominated by bushes, or pastures at higher elevations; at lower altitudes occurs in extensive agricultural valleys near human settlements. On non-breeding grounds in valleys and plains found in variety of habitats, including gardens and abandoned cultivation.**Food and Feeding.** Mostly insects, such as crickets and grasshoppers (Orthoptera), beetles (Coleoptera) and caterpillars; small vertebrates, such as lizards, frogs, birds and small rodents, may also be consumed. Hunts from open perch, taking prey mostly on ground; some insects hawked in air. Impales prey; keeps larder.**Breeding.** Season Jun–Jul in India and Apr–Jul/Aug (mainly May–Jun) in S China (Xizang); possibly two broods in China but proof lacking. Territorial; residents maintain territory throughout year. Nest a bulky, rather untidy-looking cup, external diameter 13–20 cm and height c. 8–5 cm, made mainly from twigs and grass, placed c. 2 m up in small tree or bush, either isolated or in streamside thicket or row of trees. Clutch 4–6 eggs, pale greyish with brown or grey-brown blotches and spots, and with numerous lavender marks; no information on incubation and fledging periods.**Movements.** Most individuals winter at lower altitudes within breeding range. NW race *lahulensis* appears to be resident or to descend to foothills of Himalayas, whereas nominate race either undertakes altitudinal movements or migrates to non-breeding areas farther S. Non-breeders recorded from plains of S China, India S to West Bengal, Bangladesh, Myanmar, N Thailand, Laos and N Vietnam. Migrants arrive back on breeding territories by early May. Chinese breeders appear to be mainly altitudinal migrants within their breeding range.**Status and Conservation.** Not globally threatened. Not uncommon. Population trends not known, but apparently not at any immediate risk. High-elevation habitat considered more secure than lower-lying ones.**Bibliography.** Biswas (1962), Chen Fuguan *et al.* (1998), Grimm (2006), Harris & Franklin (2000), Lefranc & Worfolk (1997), Li Guiyuan *et al.* (1976), Luo Shiyu *et al.* (1992), MacKinnon & Phillips (2000), McCarthy (2006), Olivier (1944), Rasmussen & Anderton (2005b), Robson (2000b), Tryjanowski & Reino (2004), Vaurie (1955, 1972).

12. Mountain Shrike

Lanius validirostris

French: Pie-grièche des Philippines

German: Philippinenwürger

Spanish: Alcaudón Filipino

Other common names: Philippine/Strong-billed/Grey-capped Shrike

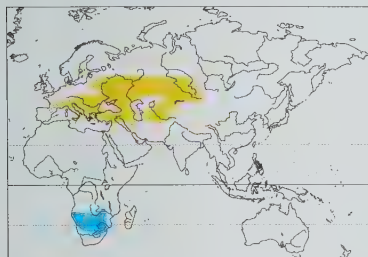

Taxonomy. *Lanius validirostris* Ogilvie-Grant, 1894, mountains of north Luzon, Philippines.Possibly part of the superspecies formed by *L. schach* and *L. tephronotus*, being very similar to latter, especially in plumage. Proposed race *quartus* (from Duminagat, Mt Malindang, on Mindanao) considered synonymous with *hachisuka*. Three subspecies recognized.**Subspecies and Distribution.***L. v. validirostris* Ogilvie-Grant, 1894 – N Luzon (Cordillera and N Sierra Madre), in N Philippines.*L. v. tertius* Salomonsen, 1953 – N Mindoro (Mt Halcon and Mt Dulungan), in NC Philippines.*L. v. hachisuka* Ripley, 1949 – Mindanao (Mt Malindang, mountains of Misamis Oriental, Mt Kitanglad and Civolig, Mt Apo), in S Philippines.**Descriptive notes.** 20–22.5 cm; 34–44.9 g. A medium-sized to large shrike with longish tail and relatively strong and heavy bill. Nominant race has thin black band above bill extending into black facial mask through lores and eye to rear of ear-coverts, narrow whitish supercilium (often short and barely noticeable); crown, nape and mantle to uppertail-coverts dark grey, rump and uppertail-coverts sometimes with rufous tinge; upperwing uniform dark brown with paler fringes, tail dark brown; chin, throat and breast white, breast sometimes faintly rufous tinged, rest of underparts whitish or greyish-white, rufous-brown on flanks and undertail-coverts; iris dark brown; bill and legs black. Sexes alike in plumage, female slightly smaller than male. Juvenile/immature has facial mask blackish-brown and reduced in extent, wing and tail similar to adult, crown and upperparts greyish-brown or brown with dark barring, underparts greyish-white with rufous flanks, side of breast and breast, and vermiculated dark, bill grey-brown with dark horn-coloured base of lower mandible. Race *tertius* is smaller than nominate, with pale rusty wash on breast and belly, deeper rufous on flanks and undertail-coverts; *hachisuka* is intermediate in size between other two races, richer rusty and rufous below than previous. **Voice.** Song like that of a sylviid warbler, incorporating high-pitched whistles. Call a series of harsh, loud “piaaoo” or “chaaoo” whistles, repeated two times per second for period of 4–5 seconds; abrupt, harsh “chrr-chrr-chrr” alarm.**Habitat.** Clearings within and edges of tropical montane oak (*Quercus*) and pine (*Pinus*) forest, open secondary growth and woodland, and grassland with shrubs; 1200–2400 m.**Food and Feeding.** Arthropods, mostly insects; beetles (Coleoptera) probably important in diet, and thick bill possibly adapted for cracking extremely hard-bodied beetles. Occurs singly or in pairs, fairly conspicuous; behaviour said to be same as that of *L. bucephalus*. Hunts by perching upright on exposed perch on top of bush or tree, from where it dives down on to prey; probably also hops on ground. No other information available.**Breeding.** Birds with enlarged gonads in Feb, Mar, May and Jun, and pair feeding juveniles in mid-May. Probably monogamous and territorial. No further information.**Movements.** No information. Possibly resident, with some local altitudinal movements.**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Mindoro EBA, in Luzon EBA, and in Mindanao and the Eastern Visayas EBA. Generally considered uncommon throughout its small range, but now appears fairly common in upland habitat that is not under pressure from humans. Although this species' area of occurrence is small, its habitat is apparently secure and it is present throughout this habitat. Species requires basic biological research and population surveys. Probably not at any immediate risk.**Bibliography.** Anon. (2007m), Butchart & Stattersfield (2004), Collar *et al.* (1999), Delacour & Mayr (1946), Dickinson *et al.* (1991), Hahnke (1998), Harris & Franklin (2000), Kennedy *et al.* (2000), McGregor (1909), Meyer de Schauensee & duPont (1962), duPont (1971), Poulsen (1995), Rand & Rabor (1958, 1960), Ripley & Rabor (1961), Sibley & Monroe (1990), Stattersfield & Capper (2000).

PLATE 59

13. Lesser Grey Shrike

*Lanius minor***French:** Pie-grièche à poitrine rose **German:** Schwarzstirnwürger **Spanish:** Alcaudón Chico**Taxonomy.** *Lanius minor* J. F. Gmelin, 1788, Italy, Spain, Russia = Italy.Affiliations uncertain; nearest relative seems to be *L. schach*. Geographical variation insignificant and clinal, plumage coloration becoming paler and size larger from W to E; species sometimes treated as monotypic. Two subspecies currently recognized.**Subspecies and Distribution.***L. m. minor* J. F. Gmelin, 1788 – breeds NE Spain and S France, Italy (from Piedmont E to Venezia, S patchily to Sicily), E Austria, Slovakia, Hungary and Balkans (S to N Greece and E to Black Sea), also S Lithuania, Belarus and SW Russia (E to Urals, S to Crimea and Caucasus), S to Turkey, N Syria, Lebanon and N Iraq; non-breeding S Africa.*L. m. turanicus* Fedushin, 1927 – breeds W Siberia (E of Ural Mts) E to Russian Altai and extreme NW China (NW Xinjiang), S to Azerbaijan and NW & N Iran, N Turkmenistan and NE Afghanistan; non-breeding S Africa.**Descriptive notes.** 19–23 cm; 41–61 g. A medium-sized shrike with long wings (long primary extension), relatively short, rounded tail, and stubby-looking bill. Male nominate race has black forehead, lores and facial mask (extending to nape side), grey to bluish-grey crown, nape and upperparts; upperwing black, conspicuous broad white band across primaries (near base), tail black, outer feathers tipped white, outer two feather pairs entirely or almost entirely white; chin and throat white, underparts pinkish-white, undertail-coverts white; iris brown or dark brown; bill black; legs blackish. Distinguished from *L. excubitor*and *L. meridionalis* mainly by more compact shape (shorter tail, shorter bill), longer wings, more black on forehead, lack of pale supercilium, little or no white on scapulars, from former additionally by pinkish (not pure white) underparts. Female is similar to male but slightly duller, facial mask greyer or browner, especially on forehead, next-to-outermost tail feather (T5) with more black (nearly 93% of 72 females had black spot on T5, 67% of 97 males lacked spot). Juvenile is pale brownish-grey above, finely and rather indistinctly barred brown (feathers with darker subterminal band), with quite long black-brown patch on ear-coverts, whitish tips of scapulars (can form pale patch on folded wing), wing feathers tipped buffish, primary patch as adult's, underparts creamy or off-white, sometimes faint bars on flanks, bill flesh-grey at base; first-winter plumage similar to adult but duller, often tinged browner above, with forehead greyish (not black), wing and tail as juvenile, sometimes a hint of faint barring above and/or below. Race *turanicus* is larger and paler than nominate, and upperparts of immature and first-winter rather brownish-buff, less greyish. **VOICE.** Territorial calls are long series of "djejek-dschejek-dschijek...", "kerrib-kerrib...", "tschertscherb, tschertscherb..." or "tschilip-tschilip...", often given during display-flights. Aggression calls include "keeee" or "rrrrr"; alarm a repeated "kshek", "gä" or "geer"; "krett" note described as contact, and begging call (female and young) "gäh-gäh..." or similar. Male song, used in intrasexual displays and courtship by unmated males without territory during breeding season or during non-breeding, consists of mixture of fluting warbles and harsh chatters, usually introduced by characteristic "krjé", and incorporating songs of wide range of other species e.g. from finches (Fringillidae), larks (Alaudidae) and tits (Paridae) to waders (Charadriiformes) and partridges (Phasianidae), and even crow (Corvidae) calls and barking of dogs; similar to but somewhat louder than that of congeners.**Habitat.** Open habitat with plenty of scattered or grouped trees, and fewer bushes; requires presence of features offering perches, shade and accessible food. Breeding habitats in Europe include extensively managed orchards, potato, beetroot and melon fields, and tobacco fields, as well as vineyards and meadows; tall trees necessary for nesting. Prefers open or disturbed lowland and hilly areas to 700 m, rarely to 900 m in C Europe; to 1500 m in Russia, and even up to 2200 m in Kazakhstan. Need for drier and sunnier conditions than those tolerated by other European shrikes possibly connected with more specialized diet of large insects. In S African non-breeding quarters inhabits semi-arid savanna and thornveld; Kalahari region in Botswana holds locally dense population, mainly in dry acacia (*Acacia*) thornbush country and open acacia parkland.**Food and Feeding.** Almost exclusively insectivorous, but spiders (Araneae) also consumed; vertebrates such as small mammals or birds taken only very rarely. Prefers mostly larger insects such as crickets (Gryllidae), mole-crickets (Gryllotalpidae) and other Orthoptera, and larger beetles (Coleoptera), average body length of prey reaching 22.7 mm in some studies, but eats caterpillars also; beetles mainly coprophagous scarabaeids and zoophagous carabids, and diet dominated by cockchafers (*Melolontha melolontha*) during outbreaks of this scarabaeid. Of 1382 prey items in C Slovakia, 99.8% were invertebrates (of 92 species), of which 28.2% crickets, 18.2% scarabaeids, 18.3% carabids, 11.9% grasshoppers (Acrididae) and bush-crickets (Tettigoniidae), and 5.9% lepidopteran larvae. Usually forages alone, or pair-members feed in close proximity. Uses sit-and-wait foraging technique, utilizing variety of lookout perches 2–15 m above ground, e.g. wires, fence lines, tree branches, very occasionally houses or other buildings; most insects taken on the ground, in fine weather also caught in air (slow-flying ones, e.g. bibionid flies, cockchafers). Very often hovers in manner of a kestrel (*Falco*), much more so than any other European shrike; also hops on ground like a wheatear (*Oenanthe*), particularly in wet weather. Rarely impales prey, although some individuals do so more regularly; during temporary increases in food supply, however, may keep larders more frequently and impale items even on unusual substrates.**Breeding.** Laying May to early Jun (in C Europe, mean 17th–19th May), replacement clutches to early Jul; one brood. Monogamous; territorial, but breeds often in loose groups, with recorded maximum of 4 pairs/ha in traditionally farmed orchard. Nest built by both sexes, a well-made structure with loose foundation of twigs, grass, rootlets, string, etc., often with high proportion of green plants (especially aromatic species), lined with rootlets, feathers and hair, occasionally unlined, placed on lateral branch of tree, usually fruit tree or poplar (*Populus*), at 2.5–20 m but generally high above ground (mean of 401 nests in C Europe 8.5 m); territory size 2.9–14 ha. Clutch 3–7 eggs, mainly 5–6 (no known geographical variation in clutch size), pale bluish-green, with olive-brown spots concentrated toward broad end, eggs laid one daily; size of replacement

clutches significantly smaller than first ones; incubation by female, fed on and away from nest by male, period 14–16 days; chicks brooded by female, fed by both sexes, nestling period 14–19 days, mostly 16–18 days; young independent 2–3 weeks after fledging, but remain with parents for c. 2 months or longer. Breeding success relatively high in optimal condition, e.g. 4.9–6 young fledged from each of 117 nests in C Europe; rarely, seven chicks raised from single brood. First breeding at 1 year.

Movements. Long-distance migrant, entire breeding population wintering in S Africa (within a range five times smaller than breeding range), from extreme S Angola and Namibia E to S Mozambique and parts of N South Africa. Those breeding in NW China may even travel nearly 12,000 km to Namibia. In autumn, birds from W of range initially head SE through Greece and Aegean Sea, all populations entering Africa on narrow front, principally through Egypt and Arabian Peninsula. Movement begins late Jul and Aug in C & W Europe, passage reaching peak in second half Aug; crosses Aegean Sea up to end Sept and Egypt to late Nov, arriving in winter quarters from late Oct (Zimbabwe) to late Nov (South Africa). Some pass over high-lying terrain, E birds recorded at up to 3400 m. Return migration in spring along similar route but a little farther E, e.g. in Zimbabwe E of c. 30° E (W of this longitude in autumn); starts late Mar, main passage in Zambia first half Apr, main exodus apparently via E Africa, Ethiopia and Somalia and continuing through Middle East. In C Europe (Slovakia), earliest arrival on breeding grounds in late Apr to mid-May, sometimes when still winter conditions there; arrival in W Siberia mid-May. Vagrants recorded in e.g. Scandinavia, Britain, Ireland, Channel Is (Jersey, Alderney), Heligoland, W & NW Africa and offshore islands, C Siberia (Mirnoye), Pakistan, Aldabra and Madagascar.**Status and Conservation.** Not globally threatened. Locally common to rare. Maximum of 320,000 breeding pairs thought to occur in Europe, with strongholds in Russia and Turkey (each with up to 200,000 pairs) and Romania (up to 70,000); from roadside counts in S Africa, total world population in mid-1990s estimated at 5,000,000–7,000,000 individuals. Decreasing trends reported in Europe, and now extinct in many countries of N, W & C Europe, e.g. last bred in Belgium in 1930, in Luxembourg in 1930s, in Germany (in S) in 1980s, in Switzerland mid-1980s, in Czech Republic in 1990s, and in Poland (SE) in early 1990s; only small population remaining in Austria (4–10 pairs in extreme E), and only isolated populations (up to 30–50 pairs) survive in Spain and France. Range contraction towards SE combined with decline in numbers in most European countries evidently part of longer-term trend apparent since middle of 19th century and later, during 1970–1990, affecting up to 30% or more of European population. Few data on status of populations farther E, in Asia, but seems to be fairly common. Protected in most countries; in some listed as "highly endangered", in others regarded as "vulnerable" or "endangered". Heavy use of fertilizers since middle of 20th century has led to increase in vegetation cover, causing wetter and colder micro-climate close to soil, this, in turn, having negative effect on the large arthropod fauna on which this species relies. It would benefit from a decrease in use of agricultural pesticides and from the maintenance of traditional farming methods, with old orchards.**Bibliography.** Chacón (1996), Clancey (1980a), Cramp & Perrins (1993), Dementiev *et al.* (1954b, 1968), Dowsett (1971), Dvorak *et al.* (1993), Haensel (1963, 1965), Haffer (1993h), Hagemeijer & Blair (1997), Hantge (1957), Harris & Arnott (1988), Harris & Franklin (2000), Hernández (1993a), Herremans (1998), Hockey *et al.* (2005), Hoi *et al.* (1997), Horvath (1959), Isenmann & Debout (2000), Kren (2000), Kristin (1991, 1995), Kristin & Zilinec (1998), Kristin, Hoi *et al.* (2000, 2007), Kristin, Valera *et al.* (2007), Kristin, Vanhinsbergh *et al.* (1998), Lefranc (1978, 1993, 1995), Lotti (1988), Niehuis (1968), Panov (1983), Patrikeev (2004), Rashkevich (1956), Ristow (1966, 1977), Rogacheva (1992), Roselaar (1995), Salvo (1988), Samwald & Samwald (1993), Schmick (1980), Scott *et al.* (1975), Shirihai (1996), Tucker & Heath (1994), Ullrich (1971), Valera *et al.* (2001), Warnke (1958), Western (1992), Wirtitsch *et al.* (2001), Yeatman-Berthelot (1995).

14. Loggerhead Shrike

*Lanius ludovicianus***French:** Pie-grièche migratrice **German:** Louisianawürger **Spanish:** Alcaudón Americano
Other common names: Migrant Shrike, Butcherbird**Taxonomy.** *Lanius ludovicianus* Linnaeus, 1766, Louisiana, USA.Forms a superspecies with *L. excubitor*, *L. meridionalis* and *L. sphenocercus*. Recent molecular-genetic studies suggest that present species is possibly closest to *L. meridionalis*, but further research required. Races intergrade, making subspecific delimitation difficult. Other proposed races include, in USA, *gambeli* (described from Calaveras County, in EC California), *nevadensis* (Inyo County, in E California) and *sonoriensis* (Chiricahua Mts, in SE Arizona), all subsumed in *excubitorides*; and *miamensis* (Cutler, Miami-Dade County, in SE Florida), merged with nominate; and, in Mexico, *nelsoni* (S Baja California), which is synonymized with *mexicanus*. Seven subspecies currently recognized.**Subspecies and Distribution.***L. l. excubitorides* Swainson, 1832 – breeds SW Canada (S British Columbia, C Alberta, S Saskatchewan and SW Manitoba) S in W USA to E Washington, extreme S Oregon and S Idaho and to California, Arizona, New Mexico, Texas (except NE), E to North Dakota, South Dakota, Nebraska, Kansas and W Oklahoma; non-breeding in S parts of range and S to W Mexico (including Baja California).*L. l. grinnelli* Oberholser, 1919 – extreme S California (S from San Diego County) S to extreme NW Mexico (C Baja California Norte).*L. l. anthonyi* Mearns, 1898 – Channel Is (Santa Rosa, Santa Cruz, Santa Catalina), off S California.*L. l. mearnsi* Ridgway, 1903 – San Clemente I, off S California.*L. l. migrans* Palmer, 1898 – breeds SE Canada (S Ontario, S Quebec, S Michigan) and, in USA, from E edge of Great Plains (E from Nebraska, Kansas, Oklahoma and NE Texas) E to New York and Atlantic coast, and S into Mississippi Valley to N Mississippi, Arkansas and N Louisiana; non-breeding in S of range and S to Gulf Coast states and E coast of Mexico.*L. l. ludovicianus* Linnaeus, 1766 – E & S USA (E of Appalachian Mts) from North Carolina S to Gulf Coast states and S tip of Florida.*L. l. mexicanus* C. L. Brehm, 1854 – W & C Mexico (including S Baja California) S to Oaxaca.**Descriptive notes.** 18–22 cm; 43–54 g. A medium-sized shrike with medium-length tail. Male nominate race has black facial mask from lores and (very narrowly) over base of bill back to rear ear-coverts, sometimes very narrow whitish supercilium (often invisible); forehead and crown to lower back variably slate-grey to pale grey (palest in S), rump and uppertail-coverts slightly paler, scapulars broadly tipped white; upperwing black, broad white tips on tertials and secondaries, wide white bar across primaries (near bases); tail black, all except central feather pair tipped white, outer web of outer two pairs entirely white (sometimes some black on T5); throat and underparts whitish, flanks

sometimes washed pale grey, occasionally some faint darker vermiculation on breast; iris dark brown; bill black, in non-breeding season often pale base of lower mandible; legs blackish. Differs from *L. excubitor* mainly in smaller size (10–15% smaller), shorter bill with less pronounced hook. Female is very similar to male, but often lores duller (grey feather bases), upperparts less bluish, sometimes more greyish below (breast feathers with grey or brown shafts), legs browner. Juvenile is paler than adult, generally light brownish-grey with fine dark vermiculation above and below, facial mask narrower and browner, cinnamon-

buff tips of greater upperwing-coverts (buffish wingbar), smaller white primary patch than adult, pale base of lower mandible. Races differ mainly in plumage coloration and size: *migrans* is on average slightly paler above than nominate, a shade greyer below, with smaller bill; *excubitorides* is paler above than other races (except S populations of nominate, “*miamicensis*”), white on lower rump and uppertail-coverts, usually has some white in superciliary area (supercilium often fairly prominent); *grinnelli* is dark grey above, with little or no white in superciliary area, smaller white tail tips, grey below; *anthonyi* is darker above than nominate, with less white in scapulars, less white in tail and wing, has pale grey rump and uppertail-coverts; *nearnsi* is similar to previous but smaller, slightly darker above but paler below, rump whiter (not so grey), scapulars mostly white, bill somewhat shorter and with tip less hooked; *mexicanus* is dark above, rump variable (white to pale grey or medium grey), more greyish (less white) below than nominate, bill relatively slender. Voice. Huge variety of calls. Repeated harsh screeching “tscheer-tscheer...”, and sharp “bzeek-bzeek” as territorial calls, latter as 4–12 notes diminishing in intensity; harsh, buzzy “tuubzt” or “tzzweet” notes probably used also in territorial disputes; alarm “aak” (aerial predator), “jaa” (for terrestrial danger), and “keer” and “kzzz” sounds; in defence, e.g. of nest, may give “schgra-a-a”. Begging calls of female and juvenile described as “naaaa-naaa...”, also “tsp” (very young nestlings) and husky repeated “teheek” or “teheep” (older nestlings). Song consists of series of notes of two or three syllables with metallic quality, e.g. “krrr-di” or “jee-uk”, repeated at short intervals; some duetting by partners reported; not known to mimic other species.

Habitat. Breeds in open country with short vegetation, generally below 2000 m elevation. Prefers active pastures with fencerows, mowed roadsides and parks, golf courses, cemeteries, open woodland, old orchards, and agricultural fields. Usually avoids row crops, but has been observed in corn fields in Midwest. In winter, N populations withdraw to areas with infrequent snow cover; in non-breeding season, habitat also includes mowed and idle crop fields with nearby trees or shrubs (for shelter from aerial predators). Breeding and winter territories usually include impaling sites such as thorn trees and barbed-wire fences.

Food and Feeding. Almost 70% insectivorous, more so than *L. excubitor*. Chief among prey items are grasshoppers and crickets (Orthoptera) and beetles (Coleoptera), but diet includes also spiders (Araneae), crayfish (Decapoda), frogs, mice (Muridae) and small birds, also carrion (including roadkills); other small vertebrates, such as lizards and snakes consumed less frequently. Small mammals and birds taken more often in winter, when insects less available. Solitary hunter; pair-members may hunt same area, but without co-operation. Usually sits and waits on exposed perch 1–15 m above ground, or hovers over open fields; often uses fence lines, utility lines and poles as hunting perches, often adopting nearly horizontal posture, with tail cocked at upward angle. Most prey caught on ground, but flying insects captured also in air. Reduced prey base in winter months often results in territory at that season being larger than breeding territory.

Breeding. Breeds earlier than most other passerines. Laying mainly Feb–Jul; late May to Jul in N of range, but in S eggs found as early as mid-Jan in Florida and nesting begins mid-Feb in S Texas and Louisiana; multiple broods common in S. Monogamous. Territorial; occasionally nests in loose groups, e.g. seven pairs found nesting within 1 square mile (259 ha) in E Colorado. Nest built by female, a bulky cup constructed from twigs, bark strips and grass, lined with rootlets, moss, fine grasses, animal fur and feathers, sited from below 1 m to up to 3 m above ground and well hidden in tree fork or on lateral branch beneath canopy of isolated tree or thick shrub; thorny tree such as acacia (*Acacia*) or hawthorn (*Crataegus*) selected where available, preferring trees not rubbed by livestock, and in arid W nests in sagebrush (*Artemisia*) or cactus, e.g. cholla or prickly-pear (*Opuntia*); territory size variable (dependent on availability of nest-sites, prey and foraging perches), from 2.7 ha (Alberta, in Canada) to 25 ha or more, average 6–9 ha. Clutch 3–9 eggs, larger clutches in N latitudes, grey-buff with darker splotches at large end; replacements laid if clutch lost; incubation by female, fed on and away from nest by male, period mainly 15–17 days; chicks brooded by female, fed by both sexes, nestling period 17–20 days; juveniles able to feed themselves from c. 2 weeks, independent from c. 4 weeks, sometimes stay with parents for longer (up to c. 3 months). Nests occasionally parasitized by Brown-headed Cowbird (*Molothrus ater*). Breeding success relatively high, 56%; chief causes of nest failure are predators and severe weather.

Movements. N populations migratory, most wintering S of latitude 40° N; populations in extreme N of range (W Canada) possibly migrate farthest S, to Mexico. Most S populations resident on breeding territories. Migrates individually, but migrating family groups may be encountered in autumn; diurnal low-level migrant, individuals may travel 70–80 km/day, feeding along the way. Migrants leave breeding grounds in N extremes and higher altitudes from mid-Jul, stragglers not until as late as Nov; Christmas Bird Count data suggest that highest concentrations of this species in winter months are found in US states of Texas, Louisiana, Mississippi and Alabama. Spring return begins in Feb; in E Colorado a few arrive late Feb, and arrivals through rest of range continue through late May.

Status and Conservation. Not globally threatened. Rare to locally fairly common. Decreasing trend in E (E of R Mississippi); some W populations appear stable, but not well studied. The species is listed as “threatened” or “endangered” in whole of Canadian range; in USA, as “endangered” in Wisconsin, Indiana, Ohio, Vermont, New York, New Hampshire, Massachusetts, Pennsylvania, New Jersey and Maryland, and as “threatened” in Minnesota, Illinois and Virginia; listed as “Species of Special Concern” in most other states of USA. Of the migratory races, *migrans* is the most endangered. Race *nearnsi*, confined to small island of San Clemente, is listed as “endangered”. Factors affecting population declines have not been positively identified. Although rates of breeding success high, and winter survival (more than 38%) appears sufficient for species’ viability, numbers in E areas continue to fall; Active recovery programmes and captive-breeding programmes have been initiated in Ontario and Idaho, and on San Clemente I. Reduction in use of agricultural and domestic pesticides and the restoration of hedgerows at field and pasture edges would be positive steps in helping to increase numbers. Research priorities include identification of causative factors in population decline; ability to determine sex and races in the field remains difficult, and often impossible.

15. Great Grey Shrike

Lanius excubitor

French: Pie-grièche grise

German: Raubwürger

Spanish: Alcaudón Norteño

Other common names: Grey Shrike; Northern Shrike (*borealis*, *invictus*); North Siberian Shrike (*sibiricus*); Steppe Shrike (*homeyeri*); Altai Shrike (*mollis*)

Taxonomy. *Lanius excubitor* Linnaeus, 1758, Europe = Sweden.

Forms a superspecies with *L. ludovicianus*, *L. meridionalis* and *L. sphenocercus*. Sometimes treated as conspecific with *L. meridionalis*, but the two overlap slightly in range, with little intergradation, in C Asia. Geographical variation complex and not fully understood, and obscured by individual variation and intergradation between races; in Nearctic, *invictus* apparently interbreeds with *borealis* in C Canada (NE Manitoba and N Ontario) and is sometimes synonymized with latter; *sibiricus* and *mollis* intergrade in NW Mongolia. Proposed race *leucopterus* (from upper R Naryn, in Kyrgyzstan) regarded as synonymous with *homeyeri*. Eight subspecies provisionally recognized.

Subspecies and Distribution.

L. e. invictus Grinnell, 1900 – breeds Alaska (except N) and NW & NC Canada (Yukon and Northwest Territories, and extreme N British Columbia E to N Ontario); non-breeding S Canada and most of W & C USA.

L. e. borealis Vieillot, 1808 – breeds NE Canada (N Ontario and N & C Quebec E to Labrador); non-breeding SE Canada and C & E USA.

L. e. excubitor Linnaeus, 1758 – breeds N, C & NE Europe (E from Scandinavia and C France) E to NW Siberia (lower R Ob), S to S Russia (Kazan area); non-breeding S Scandinavia, Britain and W & S France E to Asia Minor, Caucasus and Transcaucasia.

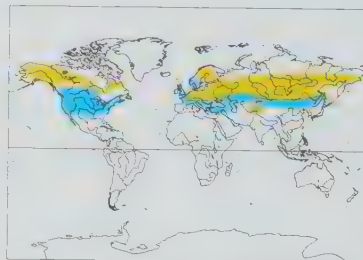

L. e. sibiricus Bogdanov, 1881 – breeds C & E Siberia E to Kolyma Basin, Anadyrland and Chukotsk Peninsula, S to L Baikal, N Mongolia and SE Russia (N Amurland), possibly also N Kurils (Paramushir I); non-breeding SC Siberia, Mongolia, NE China (N Manchuria, perhaps N Hebei) and Ussuriland.

L. e. homeyeri Cabanis, 1873 – breeds SE Europe (E Balkans, Bulgaria, S Romania, Ukraine E to foothills of S Urals) and SW Siberia (E to N foothills of Altai, including Naryn region); non-breeding SW & C Asia.

L. e. mollis Eversmann, 1853 – breeds CS Russia (Altai and Sayan Mts) and NW Mongolia; non-breeding also N China.

L. e. funereus Menzbier, 1894 – Dzhungarian Alatau Mts (E Kazakhstan) and S & E Tien Shan (Kyrgyzstan–NW China).

L. e. bianchii E. J. O. Hartert, 1907 – breeds Sakhalin I and S Kuril Is; non-breeding N Japan (Hokkaido, rarely farther S).

Descriptive notes. 24–25 cm; 48–81 g. A rather large shrike with medium-length tail; white of scapulars, wing and tail conspicuous in flight. Male nominate race has narrow black face-mask (thin dark area above bill barely noticeable) extending back to rear of ear-coverts, thin whitish supercilium (often indistinct or lacking); top of head, nape and upperparts to lower back pale grey with variable bluish tinge, rump and uppertail-coverts often slightly paler, scapulars white; upperwing black, prominent white patch across bases of primaries, often another (narrower) white patch at base of secondaries, flight-feathers and tertials

tipped white; tail black, outer feather pair white (sometimes some black on inner web), adjacent rectrices with progressively decreasing amount of white; throat and underparts white, in fresh plumage occasionally a hint of pink tinge on breast; iris brown or dark brown; bill black; legs blackish. Distinguished from similar *L. meridionalis* (nominate race) mainly by much paler plumage, indistinct or non-existent supercilium, more white in wing, also by slightly longer wings, shorter and less robust bill and shorter legs. Female is very like male but with less white in plumage (white wing patches slightly smaller; whitish tips of wing feathers narrower, scapulars with more grey tones), greyer (not so pure white) underparts sometimes with hint of vermiculation on upper breast. Juvenile is generally more brownish-grey, usually faintly barred dark brown from nape to uppertail-coverts, with facial mask browner, greater coverts pale-tipped, whitish below, grey-brown wash on breast and flanks, narrowly vermiculated brown, bill brownish-grey. Races differ in plumage and in body size: *homeyeri* is paler than nominate, rump and uppertail-coverts whitish, white supercilium more obvious, extensive white in wing, more white in tail (including at base of central feather pair); *sibiricus* is tinged ochre above, lightly vermiculated below; *mollis* is darker than previous, has smaller white wing patch, underparts more buff and more strongly vermiculated; *funereus* is larger than others, in plumage similar to previous but darker, with underparts more brownish-grey and more heavily vermiculated; *bianchii* is small, similar in plumage to *sibiricus* but paler and greyer, less buffy, above, and less vermiculated below; *borealis* is similar to nominate, but rump and uppertail-coverts paler, supercilium more prominent, white in wing always restricted to primaries, greyer underparts extensively vermiculated dark, juvenile much darker and browner all over and more strongly barred below than juvenile nominate; *invictus* is very like last, perhaps slightly paler above, supercilium stronger, rump and uppertail-coverts white, underparts less vermiculated. Voice. Song consists of short, repeated verses, interrupted by longer intervals of silence; usually introduced with “trrr” or “prrr” (sometimes varied to “trrr-tr-trrr”) for alarm, but different alarm, “ääk”, “kwää” or “wäääk”, used in parent–offspring interactions; in territorial conflicts between males “ghirr” recorded. Notes such as “kwiet” and “triet” and also more vocal “chlip”, “tlück” or “tluck”, in courtship behaviour; also in duets by partners, “chli”–“ip” or “triet”–“chlip”, sometimes first note given by one partner and second by other partner, or both notes by just one of the two, followed by two notes by the other.

Habitat. Breeds in subarctic and temperate climates in open country with trees, bushes, fence posts and powerlines; N populations in clearings in taiga or in transition zone from taiga to tundra and forest edge; sometimes also on marshland and peat bogs. Sparse and low vegetation an impor-

tant component, typical perch densities in C & N Europe 5–15 perches/ha. Suitable perches are provided by isolated trees, small groves, bushes, and also pylons, electric wires and fences. Habitats used in non-breeding areas similar to those when breeding, but meadows more important outside breeding season.

Food and Feeding. Highly opportunistic and flexible in use of different food spectra, as well as in hunting tactics. Diet consists mainly of small vertebrates and large arthropods. Voles (Microtinae) appear to be most frequent vertebrate prey, usually in excess of 50% (sometimes as much as 90%) of total biomass taken; small birds, shrews (Soricidae), lizards and frogs also relatively frequent prey. Large insects (seldom more than 15% of total biomass consumed) chiefly beetles (Coleoptera), grasshoppers and crickets (Orthoptera), and wasps and bees (Hymenoptera); various other insects and invertebrates recorded as food, including arachnids, worms (Oligochaeta), snails (Gastropoda) and crayfish (Decapoda). Carrion occasionally recorded; also small fruits. Usually forages and perches alone, or partners feed in close proximity to each other. Uses sit-and-wait technique. Utilizes variety of lookout perches 2–15 m high, including wires, fence lines, tree branches; dives down on to prey on ground. Also, very often hovers in manner of a kestrel (*Falco*). Very frequently impales prey, although some individuals impale more regularly in larders than others. During mating period, males impaled more prey before mating than they did afterwards, the majority of cached prey was on borders of territories and in visible places, and a large part of the food was left uneaten, all of which indicates that during mating period impaling behaviour has a signalling function. During breeding stages, in contrast, impaling was used primarily as a means of storing food: distance from larders to nests decreased, more prey were stored in well-concealed sites, and larger proportion of stored food was consumed.

Breeding. Laying from end Mar to end May, replacement clutches to early Jul; Mar–Jun in C Europe, Apr–May in Alaska and May–Jul in E Canada (Labrador); one brood, very rarely two. Monogamous, but very rarely polygyny also observed. Strictly territorial breeder. Nest built by both sexes, a well-made structure with loose foundation of twigs, grass, rootlets, string, etc., often with high proportion of green plants, lined with rootlets, feathers and hair, placed generally high above ground (mean of 401 nests in C Europe 15.5 m) in fork or on lateral branch of tree, mainly pine (*Pinus*) or poplar (*Populus*), sometimes in dense shrub and therefore much lower (down to 0.2 m above ground), mean 1.8 m above ground in alpine areas of North America; territory size 20–350 ha. Clutch 3–9 eggs (usually 6–7 in Europe, 8 in North America), pale bluish-green, with olive-brown spots concentrated toward broad end; frequent replacements if previous clutch lost; incubation mainly by female, fed on and off nest by male, period 14–19 days, mostly 15–17 days; chicks brooded by female, fed initially mostly by male, later by both sexes more equally, nestling period 14–21 days, generally 15–19 days; young accompanied by parents for c. 3 weeks or more, leave natal territory usually 6–7 weeks (sometimes c. 1 month) after fledging. Nests formerly parasitized by Common Cuckoo (*Cuculus canorus*) in Europe, but no such records since late 1970s. Breeding success varies from place to place and from year to year, and is 40–55% in optimal conditions in C Europe, 3.9–6.3 young fledged per pair, and rarely nine chicks raised from single brood. First breeding in second calendar year.

Movements. Most populations migratory or at least partially so, non-breeding range including S parts of breeding range in addition to more S areas. In Old World, movements only of European populations are relatively well known; most leave breeding areas during Jul–Oct, mainly Sept–Oct, spend c. 4–5 months in non-breeding quarters, and return mainly Mar–Apr. In general, European populations migrate to wintering grounds in regions S of 60° N. Many of those breeding in SW Europe appear largely sedentary compared with populations farther E. Asian populations migrate mainly to areas in SW, C & E Asia, but recorded also as rare vagrants in N & W Europe. In North America, non-breeding range extends from S parts of Canada S in USA to NC California, C New Mexico and N Texas and, in E, S to North Carolina. Some evidence suggesting changes in migratory strategy of some populations during recent decades, e.g. increasing numbers of individuals remaining in S Fennoscandia and Poland in winter.

Status and Conservation. Not assessed. Probably not globally threatened, but until recently treated as conspecific with *L. meridionalis* and separate evaluation now required. Locally common to uncommon. Fennoscandian and Russian stronghold contains at least 330,000 breeding pairs, and future Russian censuses may reveal greater numbers; maximum density of 33 pairs/100km² in traditional farmland. Populations in rest of Europe relatively insignificant (13,000 pairs in C & E Europe, 3400 pairs in W Europe). Generally decreasing trends reported in Europe. Protected in most countries; in some listed as “highly endangered”, in more countries regarded as “vulnerable” or “endangered”. Situation in Asia and in North America not well known, but available data suggest that in both continents this is a decreasing species. Reduction in the practice of intensive agricultural management would probably be the most effective conservation measure for this shrike.

16. Southern Grey Shrike

Lanius meridionalis

French: Pie-grièche méridionale **German:** Mittelmeer-Raubwürger **Spanish:** Alcaudón Real
Other common names: Indian Grey Shrike (*lahtora*); Steppe Grey Shrike (*pallidirostris*)

Taxonomy. *Lanius meridionalis* Temminck, 1820, Provence, France.

Forms a superspecies with *L. ludovicianus*, *L. excubitor* and *L. sphenocercus*. Sometimes treated as conspecific with *L. excubitor*, but the two overlap slightly in range, with little intergradation, in C Asia. Recent molecular-genetic studies indicate that present species may be closer to *L. ludovicianus*, but this possibility requires further research. Geographical variation complex and partly clinal, races intergrading. Proposed race *jebelmarrae* (described from Jebel Marra, Darfur, in Sudan) synonymized with *leucopygus*, but may warrant recognition; further study required. Eleven subspecies currently recognized.

Subspecies and Distribution.

L. m. meridionalis Temminck, 1820 – Iberian Peninsula and S France.

L. m. koenigi E. J. O. Hartert, 1901 – Canary Is.

L. m. algeriensis Lesson, 1839 – NW Africa along Atlantic and Mediterranean coasts E to N Tunisia and N Libya (N Tripolitania, N Cyrenaica), S to coastal NW Mauritania and N Sahara.

L. m. elegans Swainson, 1832 – N & C Sahara from NE Mauritania, NW Mali, and S Tunisia E to C & S Libya, Egypt (including N & C Sinai Peninsula), NE Sudan (S to Port Sudan) and SW Israel; possibly also NE Niger.

L. m. theresae R. Meinertzhagen, 1953 – S Lebanon and N Israel.

L. m. leucopygus Ehrenberg, 1833 – S Sahara in C & S Mauritania, C Mali, C & S Niger, NE Nigeria (probably also extreme N Cameroon), S Chad and C Sudan (including Darfur).

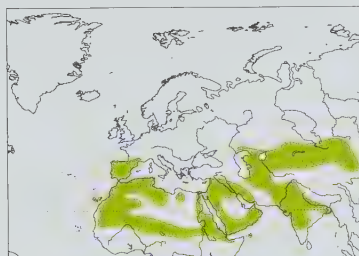

L. m. aucheri Bonaparte, 1853 – CE Sudan (S from Port Sudan), Eritrea, N Ethiopia, NW Somalia, Iraq, S Iran, Syria, SE Israel, SE Sinai Peninsula, W Arabian Peninsula and Oman.

L. m. buryi Lorenz von Liburnau & Hellmayr, 1901 – Yemen.

L. m. uncinatus P. L. Slater & Hartlaub, 1881 – Socotra I.

L. m. pallidirostris Cassin, 1852 – C Asia from NW Caspian Sea (extreme S Russia) and S Kazakhstan E to Mongolia and N China and, in W, S to NE Iran, Afghanistan, N Pakistan and W foothills of Tien Shan.

L. m. lahtora (Sykes, 1832) – Pakistan (except N) and N India (foothills of Himalayas) S to Karnataka, E to C Bangladesh.

white outer web and much white on inner web; throat white, underparts pale pinkish-grey, undertail-coverts white; iris brown or dark brown; bill and legs black. Differs from *L. excubitor* mainly in much darker colour above, pinkish underparts, distinct supercilium, smaller white wing patch, shorter wing (5–10% shorter); from *L. minor* also in relatively longer tail, shorter wing and primary extension, longer and less deep bill. Female is very like male but slightly duller, may have on average less white in plumage. Juvenile is lighter grey above than adult, but has underparts similarly pale buffish-pink, occasionally a hint of very faint dark longitudinal stripes below, facial mask dark brown, lores partly pale. Races differ mainly in plumage colour and pattern and in size: *algeriensis* is similar to nominate, but paler above and greyer below, supercilium poorly indicated, bill thicker; *koenigi* is similar to previous but smaller, with wing and tail shorter, has supercilium clearer and longer, bill on average more strongly hooked; *elegans* is much paler than last, has underparts pure white, more white in scapulars, wing and tail; *leucopygus* is similar to previous but smaller, has rump and uppertail-coverts white, underparts more creamy, not so pure white; *aucheri* is very like *elegans*, but has narrow black band above base of bill, generally less white in wing and tail; *theresae* is similar to previous, but darker grey over much of body; *buryi* also is similar, but upperparts distinctly darker, throat and underparts also somewhat darker; *uncinatus* also is similar, but has less white in scapulars, slightly longer bill; *pallidirostris* has very narrow mask, especially in front of eye, forehead pale, lores dusky, supercilium faint and not readily apparent against pale grey of crown; *lahtora* is similar to *aucheri*, but with black frontal band distinct and relatively wide, more white in wing and tail, larger bill. **VOICE.** Wide variety of calls. Repeated double “kwirick”, “sheen-sheek” or “shihk-shihk” used in territorial disputes (race *pallidirostris*), a metallic “schryck” or rolling “schrick” also recorded; these can be altered to alarm calls, “kcha-kcha...” and “weche-weche...” or more intense “sheck-sheek, sheek, sheek...”, and “djerki-djerki-djerki” and other harsh clicking and buzzing sounds probably have similar function. Repertoire includes several different trilled whistles, e.g. “dri-dri...” or harsher “trrr-trrr...”. For some races (e.g. *aucheri*) clearer whistles are used for alarm or contact, “kwiet”, “tew-dew” or ringing “trip-trip”. Parent-nesting contact calls described as “hui-hui” and begging “gaik-gaik...”, “pchee-ar” and “chee-chee-chee”. Bill-snapping recorded. Song typical of genus, harsh buzzes combined with clear whistles or relatively short warbles, with imitations of other birds included.

Habitat. Fairly open country dotted with thorny bushes in dry and warm, sunny lowlands to 1200 m. Nominative race occupies cereal-growing land with groves, hedgerows, bushes, meadows, vineyards, orchards, pasture and evergreen oak (*Quercus*) forests (“dehesas”); trees and shrubs required for nesting, as hunting perches, for territory delimitation, as food caches and for shelter against predators. Much prey is caught in the herbaceous layer, and in NW Spain this layer accounts for c. 70% of the habitat occupied; this percentage is increased in winter habitat. Other races occur in variety of arid landscapes, including semi-desert and desert, so long as some thorny vegetation is present. Less arboreal than *L. excubitor*.

Food and Feeding. Diet consists of arthropods (mostly large insects) and small vertebrates (reptiles, small mammals and birds). Nominative race prefers crickets (Gryllidae), grasshoppers (Acrididae), mole-crickets (Gryllotalpidae) and dung beetles (Scarabaeidae). Of 4527 prey items identified in 287 pellets from NW Spain, majority were insects (Coleoptera during winter, spring and autumn, and Hymenoptera in summer); other arthropods included arachnids and millipedes (Diplopoda), and vertebrates included lizards, small passerines and small mammals; arthropods 15–20 mm long on average. In terms of energy content, contribution of vertebrates was higher than that of invertebrates in all seasons except autumn (invertebrates 67.3% in autumn, in other seasons vertebrates 60.7–78%); grasshoppers and crickets the main energy source among arthropods in all seasons. Most reptiles captured were lizards and, to lesser extent, skinks (*Chalcides striatus*) and small snakes; small mammals consisted of shrews (mainly *Crocidura russula*), mice (*Apodemus sylvaticus* and *Mus spretus*) and voles (*Microtus arvalis*, *Microtus agrestis* and *Microtus lustratus*). In study in France, 5409 prey items identified in 257 pellets; 63.7% of biomass consisted of insects, of which Coleoptera 26.6%, Lepidoptera 16.2%, Orthoptera 12.9% and Hymenoptera 4.7%; vertebrates formed 21% of total prey biomass. A sit-and-wait hunter. Utilizes variety of lookouts, such as bushes, barbed wire, fences and rocks; dives down to take prey on ground. Hovering seems to be used much less frequently (by nominate race, at least). Frequently impales prey items on thorns or barbed wire. In NW Spain (nominate race), 193 cached prey were mainly orthopterans and lizards, and hawthorn (*Crataegus monogyna*) and blackthorn (*Prunus spinosa*) were preferred as impaling sites; food cached mainly during non-breeding period, and most items were used within 9 days. In Israel, males of race *aucheri* create conspicuous caches of impaled prey; cache size reflects quality of male and his territory, thereby influencing mate selection.

Breeding. Laying from Jan in Israel, from Feb in Spain and N Africa, and mainly Mar–Jul elsewhere, but season Jan–Oct (mainly Mar–Jul) in Pakistan and India, and nestlings in Mar in Somalia; two broods common in some places, and three broods recorded locally (S Israel). Monogamous; occasional records of polygyny in Negev Desert, in Israel (presumably race *aucheri*). Breeds as territorial pairs. Nest built by both sexes, that of nominate race a rather untidy deep cup made from dry material such as twigs, grass, wool and similar, often incorporating green plants such as stoechas lavender (*Lavandula stoechas*), purple viper’s bugloss (*Echium plantagineum*) and others, similar in appearance to nest of Common Blackbird (*Turdus merula*), placed on branch or in fork or outer

twigs of tree or bush, generally a thorny bush or prickly tree (e.g. *Rubus*, *Quercus ilex* or *Quercus coccifera*), usually not high above ground, e.g. range 0.3–2.2 m in S France (Crau) and average height of 65 nests 1.1 m in NW Spain; other races also typically nest low in bush; territory size 10–100 ha. Clutch 2–7 eggs (mostly 4–6), laid one daily, pale blue-green with olive-brown spots; frequent replacements if previous clutch lost; incubation by female, fed on and off nest by male, period 14–18 days, mainly 17–18 days; chicks brooded by female, fed usually by both sexes, nestling period 16–19 days; in Israel and Spain, records of female, in reaction to nest disturbance, coaxing chicks out of nest and to a hiding place in ground nearby; juveniles fed by both parents, if male polygynous fed by female only (utilizing male's food larder), independent c. 34–40 days after fledging. First breeding at 1 year.

Movements. Mostly resident. Race *pallidirostris* a long-distance migrant, but some of its S populations strictly sedentary; regular migrants winter in S & SW parts of breeding range, but can reach E Sudan, Ethiopia, N Somalia and Eritrea, leave breeding grounds in Sept, returning Mar–Apr; vagrants recorded W to Britain and S to Borneo. Some desert races, and also nominate race in France, make regular small movements; nominate mainly resident, but dispersal by young can exceed 200 km.

Status and Conservation. Not assessed. Probably not globally threatened, but until recently treated as conspecific with *L. excubitor* and separate evaluation now required. Locally common to uncommon. Nominative race numbers c. 250,000 pairs in Iberian Peninsula (but apparently decreasing) and c. 1500 pairs in France; estimated population of *koenigi* in Canary Is 1000–1500 pairs; several thousand pairs in Israel, and 5000–10,000 pairs (*aucheri*) in United Arab Emirates. Fairly common in E & SE of range, but no details of numbers. Main threats are agricultural intensification, with increased use of pesticides and herbicides; cessation of sheep grazing may lead to invasion of scrub, leaving habitat unsuitable for this species.

Bibliography. 17. Chinese Grey Shrike

Lanius sphenocercus

French: Pie-grièche géante **German:** Keilschwanzwürger **Spanish:** Alcaudón Chino
Other common names: Chinese Great Grey/Long-tailed Grey/Wedge-tailed/Large Chinese Shrike

Taxonomy. *Lanius sphenocercus* Cabanis, 1873, “probably Canton”, China.

Forms a superspecies with *L. ludovicianus*, *L. excubitor* and *L. meridionalis*. Nominative race and *giganteus* sometimes thought possibly to represent two separate species on basis of differences in size, plumage and habitat, and alleged overlap in breeding ranges without interbreeding; evidence of sympatric breeding lacking, however, and further research required. Two subspecies currently recognized.

Subspecies and Distribution.

L. s. sphenocercus Cabanis, 1873 – breeds E Mongolia E to SE Russia (Amur region and S Ussuriland), NE & NC China (Nei Mongol, NE Liaoning, probably also Heilongjiang and Jilin, S to Gansu, Shaanxi and Shanxi), N & C Korean Peninsula; non-breeding mainly E & SE China and Korea.

L. s. giganteus Przevalski, 1887 – C China (C & E Qinghai, E Xizang, N & W Sichuan).

Descriptive notes. c. 29–31 cm; 85–100 g. The largest *Lanius* shrike, with strongly graduated tail (graduation 3–4.5 cm). Nominative race has black facial mask from lores back to rear ear-coverts, rather broad white supercilium extending anteriorly over base of bill; crown, nape and upperparts medium grey, scapulars white; upperwing black, flight-feathers and tertials edged and tipped white, large and distinctive white patch across base of primaries and secondaries (very obvious in flight); tail black, three outer feather pairs almost entirely white, next two pairs inwards broadly tipped white; throat and underparts off-white, occasionally

faint pinkish or buffy tinge on breast; iris brown; bill black, greyish base of lower mandible; legs black. Distinguished from similar *L. excubitor* mainly by larger size, longer and more markedly graduated tail, more white in wing and tail. Sexes similar in plumage, female possibly slightly bigger and heavier than male. Juvenile differs from adult in having ochre-tinged upperparts with faint barring, flight-feathers and wing-coverts fringed buff, whitish underparts with ochre tinge on breast, legs pale brownish. Race *giganteus* is larger and darker than nominate, wing significantly longer, crown and upperparts dark grey, no white on forehead and supercilium, less white in wing and tail, greyish (less white) below, juvenile darker than juvenile of nominate and with stronger ochre tinge (especially below). Voice. Not well known; combination of harsh notes and whistles, and generally considered similar to that of *L. excubitor*. Territorial calls described as loud repeated “tri-rii” “tree-leece” or “tsveet-tsveet”, with emphasis often on second, drawn-out note; these calls varied to “tschrii”, “riu”, “rleece” or “chreee”, and sometimes combined with soft warbles to form song. Harsh “check-cherr”, and “keee” or “tschee” as alarm (also during flight). A “churr-churr” has been noted in parent-offspring interactions.

Habitat. Nominative race in Amur region favours broad river valleys, pastures and cultivated areas dotted with bushes and small clumps of trees, and in China known to inhabit also open steppes, semi-deserts and foothills. During non-breeding season in S Korea typically found in or beside rice fields, and the few birds seen in Japan were on cultivated plains, around open woodland or on reclaimed land with grass and shrubs. Nominative race inhabits lowlands from sea-level to c. 200 m in Russia, but in China may breed at up to 1100 m, and in winter found even to 1800 m in NW of range (Nan Shan foothills). Race *giganteus* occurs at or above timber-line, usually in stunted vegetation stands such as rhododendron (*Rhododendron*) scrub; in Xizang a high-elevation bird, nesting at c. 3000–5200 m; descends to below 4000 m in non-breeding season.

Food and Feeding. Opportunistic feeder. Diverse range of prey consisting of arthropods (mainly insects) and small vertebrates, the latter forming significant component of diet (16% of 2813 prey items in detailed study in Amurland). Food spectrum seasonally variable. In summer chiefly in-

sects, combined totals of Coleoptera (carabid beetles comprising nearly half), Orthoptera (exclusively the mole-cricket *Grylotalpa africana*) and Hymenoptera (mainly wasps and ants) accounting for c. 95 % of all invertebrate prey, also some spiders taken; among vertebrates mammals (chiefly rodents) and birds (predominantly passerines) usually hunted, but also amphibians (frogs) and lizards. In winter the percentage of mammals in diet increases. Sit-and-wait foraging technique commonly used. Prefers exposed, relatively high (2–8 m, usually 4–6 m) lookout perches, from which it swoops on to prey. Most prey caught on ground or in low vegetation, sometimes in the air; slow-flying insects seized in flight, others and birds may be chased on the wing for up to 100 m. Often hovers in manner of a Common Kestrel (*Falco tinnunculus*) for 10–30 seconds at c. 5–6 m to 15–20 m, occasionally up to 30 m, above ground. Rarely, gleans items from foliage. During breeding, male and female hunt between 10 m and 400 m (usually 40–70 m) from nest. Wedged or impaled prey regularly kept in larders, and sometimes abandoned unused. During migration and possibly in winter, migrants occupy individual feeding territories of up to 100 ha.

Breeding. Data available only for nominate race in SE Russia. Laying from second half Apr (rarely from beginning of Apr) to early Jun, fledging mainly in Jun; one brood per season. Monogamous; territorial, territories of neighbouring pairs near L Khanka (S Ussuriland) 1–2.5 km apart. Nest an open cup of variable size, made from twigs, rootlets, dried grass stems and leaves, lined with fine grass, feathers, vegetable down, sometimes animal hair and/or man-made materials, placed usually 1.2–5 m above ground in fork of small broadleaf tree or bush; territory relatively small, 2.3–5.8 ha (mean of four pairs 3.9 ha). Clutch 5–9 eggs, mean 6.8 (for 19 nests), laid one daily, creamy or greyish-white, sometimes tinged greenish or bluish, with pale brown to reddish-brown or grey spots often concentrated at large end; replacement clutches not uncommon if previous one lost; incubation by female, fed by male, period 16–19 days, mostly 16–17 days; chicks fed by both sexes, nestling period c. 19–21 days; young dependent on adults for c. 2 months after leaving nest. In one study of 11 nests, 74 eggs were laid, of which 58 hatched (78.4 %) and 45 young fledged (60.8 %).

Movements. Race *giganteus* appears to be resident, undertaking only local and altitudinal movements. Nominative race is a partial migrant; winter quarters, partly overlapping with breeding range, lie mainly in E & SE China (S to Hong Kong and W to c. 105° E) and Korea; limited number of individuals overwinter in SE Russia. Little known about migration routes, but in autumn most appear to fly in S or SW direction; some arrive on non-breeding grounds as early as Jun–Jul, but most of those breeding in Ussuriland (Russia) depart between end Aug and Oct, small numbers moving through Korean Peninsula in Sept–Oct; in E China the species is said to be seen mainly between Aug and Nov (a few spring records) in Beidaihe area, Aug–Mar in Hebei, and from Dec to Mar in Nanjing (Jiangsu). Bulk of breeding population is back on nesting grounds in Mar. Accidental winter visitor to Japan.

Status and Conservation. Not globally threatened. Status considered insufficiently known. Probably uncommon to rare throughout range. Generally occurs at low densities, in SE Russia ranging from 0.11–0.34 pairs/km² in C Amurland to 0.4–1 pair/km² in plains near L Khanka. Population in Russian Ussuriland regarded as stable, despite some evidence from 1980s of local reduction in breeding range (R Bikin basin). In the demilitarized zone in S Korea several breeding pairs (adults and fledglings observed) found in 2002, occupying probably some of the last surviving unspoiled lowland habitats. Suspected that a couple of dozens of individuals overwinter in S Korea. Occurs in Xianghai Reserve, in NE China.

(2002), Baillic *et al.* (2004), Chen Fuguan *et al.* (1998), Cheng Tsohsin (1987), Dementiev *et al.* (1954b, 1968), Etchecopar & Hüe (1983), Gore & Won Pyong-Oh (1971), Harris & Franklin (2000), Lee Kisup (2002), Lefranc & Worfolk (1997), Lei Fumin *et al.* (2004), Liu Yang & Lei Jinyu (2005), Mikhailov *et al.* (1998), Nazarov (2004), Neehaev (1976), Panov (1973, 1983), Sokolow & Vietinghoff-Scheel (1992), Tomek (2002), Vaurie (1959), Vinter (1986, 1991), Vorobiev (1954), Winter (1987), Yan Chongwei & Xu Weishu (1996).

18. Grey-backed Fiscal

Lanius excubitorius

French: Pie-grièche à dos gris **German:** Graumantelwürger **Spanish:** Alcaudón Dorsigris

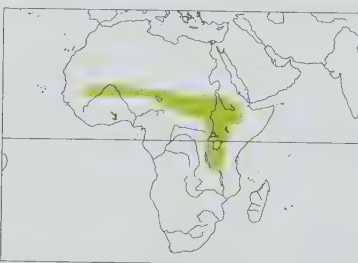

Taxonomy. *Lanius excubitorius* Prévost and Des Murs, 1847, Abyssinia and Nubia = White Nile. Forms a superspecies with *L. cabanisi*, and the two are sometimes united in subgenus *Neolanius*. Original description first used name “*excubitoroides*” but within the same publication authors altered this to “*excubitorius*”, in the mistaken belief that “*excubitoroides*” was preoccupied; as all falls technically within the original description, the emendation stands. Three subspecies recognized.

Subspecies and Distribution.

L. e. excubitorius Prévost & Des Murs, 1847 – Sahel zone of Mauritania and Mali, extreme NE Nigeria, N Cameroon, SW & SE Chad and N Central African Republic E to DR Congo, S (but not SW) Sudan and W Uganda.

L. e. intercedens Neumann, 1905 – C Ethiopia (S & W from L Tana), probably also extreme SE Sudan, S to NE Uganda and W Kenya (W of Elgeyo Escarpment).

L. e. boehmi Reichenow, 1902 – SC Uganda, extreme E DR Congo, E Rwanda, E Burundi, W Tanzania (L Victoria S patchily to L Malawi) and SW Kenya (E shores L Victoria).

Descriptive notes. 25–26 cm (nominate); male 47–63.5 g, female 46–59 g (Kenya). A large, robust shrike with long, graduated tail. Male nominate race has black forehead and lores meeting black facial mask from lores back to ear-coverts (and extending variably on to shoulder and wing), whitish supercilium; crown and nape to back grey, rump and uppertail-coverts whitish; upperwing black, very conspicuous and contrasting white patch towards base of primaries; tail black, feathers narrowly tipped white, all except central feather pair with basal half white; throat and underparts white; undertail white (most of basal half) and black; iris dark brown; bill black; legs blackish. Female is similar to male, but with dark chestnut-brown flanks (often not visible when wing closed). Juvenile has face mask brown from lores to ear-coverts, faint whitish supercilium (not always visible), top of head and upperparts greyish-brown, forehead to mantle and upper back finely barred blackish, rump and uppertail-coverts buff-white, also barred blackish, wings dark brown, white patch on primaries, upperwing-coverts slightly barred and edged buff, tertials variably tipped buff, tail dark brown with some white at base and tipped buff, underparts whitish, faintly barred on breast and flanks, bill brown.

Races differ mainly in size, darkness of upperparts and extent of white in tail: *intercedens* is larger than nominate, with longer tail, less black in tail; *boehmi* is smaller than previous but larger than nominate, has upperparts darker and more dusky grey than others. Voice. Appears to have about six different calls, consisting of harsh notes, noisy chattering, and rasping and shrill, jarring or scream-

ing notes. Two territorial calls (apparently initiated by dominant individual) are the threat call, metallic and monosyllable and sounding like “kyoir-l”, and the display call, which is like a duetting chorus uttered by defenders going for an intruder and sounds like “kyoir-l, kyoi, kyoooh”. Alarm, used also when an aerial predator close, is loud and harsh “krrr-krrr...” or “zzrit-zzzrit...”. Female (during courtship) and begging young give loud repeated “pssh”. Male often gives brief song while feeding mate and fledglings. Juvenile gives first adult-like song 75 days after fledging.

Habitat. Thorn-scrub and open acacia (*Acacia*) savanna; common in bushy and wooded grassland and open woodland, locally also entering gardens, parks, and even cultivated areas if sufficient medium-tall trees present. In study in SW Kenya (L Naivasha), breeding habitat consisted mainly of stands of yellow-barked acacia (*Acacia xanthophloea*) with understorey of perennial shrubs and Naivasha star grass (*Cynodon plectostachyus*); this type of habitat can provide high abundance of insects during dry season. Mainly in lowlands in W of range; in Kenya occurs at 1000–1900 m.

Food and Feeding. Arthropods, mainly large insects such as Lepidoptera (*Cossus* caterpillars), Hymenoptera (ants of genus *Dorylus*) and termites (Isoptera); also small vertebrates, including frogs and, occasionally, birds. Has been recorded as raiding nests of Red-billed Quelea (*Quelea quelea*). Lives in groups of up to c. 20 individuals, each of which forages alone in the group territory; at times, group-members gather at sites where food temporarily abundant, e.g. at ant swarms or at emergences of *Cossus* caterpillars from bases of acacias. Perches 2–4 m above ground on top or side of bush or tree, scanning area around; catches most prey on ground, and returns quickly to perch. Captures some insects in the air. Impales prey, and maintains caches.

Breeding. Season linked with rains and associated abundance of prey (particularly insects), usually follows rains: Feb–Mar in Mauritania and Mali, Apr–May and Aug in Sudan, and Apr and Jun in Ethiopia; in Uganda, Mar–Apr and Nov in N, May–Jul and Oct–Dec in NE and Dec–Feb in C & S; Jan, Jun–Aug and Nov in Tanzania S to EC Kenya, and attempted breeding in all months (mainly May–Nov) in SW Kenya; birds in breeding condition Apr in Cameroon and in all months in NE DR Congo. Gregarious, territorial and co-operative breeder; each group with one breeding pair, other members are helpers (males and females older than 6 months), helper females must leave natal group to attain breeding status, males appear to inherit breeding status. Mated pair separates from group, female solicits with wings drooped while making begging calls, male gives brief song during courtship feeding. Nest built by breeding female, breeding male helps with supplying of material; nest a compact cup of small sticks, twigs, grass stems, bark fibre and rootlets, mainly from acacia species, lined with fine grasses and small feathers, sometimes material from old nests reused for construction, placed 1–12 m up in thorn tree, usually on horizontal branch or in centre of tree; nest can remain empty for up to 2 weeks before egg-laying. Clutch 2–4 eggs, usually 3, variably creamy pink to olive-buff, with brown, red-brown and grey spots mainly at broad end; incubation by female, fed by male and helpers, period 13–15 days; chicks brooded by female, fed by all group-members, breeding pair providing most food, nestling period c. 20 days; young fed by all of group, totally dependent for 2 weeks after fledging, most remain in natal territory and become helpers in subsequent years.

Movements. Most populations probably resident. Regular local movements by some birds likely in W parts of range, where the species inhabits typical Sahel areas; in SE Mauritania and C Mali said to disappear or to be very rare during the rains, which suggests movements. Possibly locally migratory also in Sudan. Although earlier reports of migration to Rift Valley in Kenya considered unlikely, individuals have appeared in unexpected localities (e.g. Mau Narok, at 3000 m).

Status and Conservation. Not globally threatened. Fairly common to locally common; rare in W of range. Conservation status not properly assessed. In E range population probably stable, but surveys are recommended. Most habitats probably not under any immediate threat. Occurs in several protected areas, e.g. Murchison Falls National Park, in Uganda, and are in Serengeti National Park, in Tanzania.

Bibliography. Borrow & Demey (2001), Chapin (1954), Friedmann (1937), Fry *et al.* (2000), Gadow (1883), Hall & Moreau (1970), Harris & Franklin (2000), Lefranc & Worfolk (1997), Lewis & Pomeroy (1989), Moreau (1972), Nikolaus (1987), Olivier (1944), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

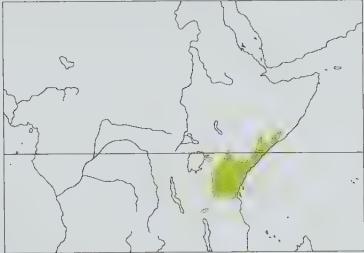

19. Long-tailed Fiscal
Lanius cabanisi

French: Pie-grièche à longue queue **Spanish:** Alcaudón Colilargo
German: Langschwanzwürger

Taxonomy. *Lanius cabanisi* E. J. O. Hartert, 1906, Mombasa, Kenya.

Forms a superspecies with *L. excubitorius*, and the two are sometimes united in subgenus *Neolanius*. Monotypic.

Distribution. S Somalia, S & SE Kenya (from E of L Victoria E to coast; occasional observations N of equator) and NE & S Tanzania (S to Kilosa and Dar es Salaam; outlying population Usanga Flats).

Descriptive notes. 26–30 cm; male 70–80 g, female 69 g. A large and robust shrike with very long, graduated tail and strong, heavy bill. Male has forehead, crown, nape and upper mantle dark blackish-brown, lores, ear-coverts and base of hindneck black (inconspicuous facial mask), mantle and upper back medium grey, becoming pale grey on lower back; rump and uppertail-coverts whitish, latter often with distinct barring at tips; upperwing dark brown, conspicuous white patch on primaries, in fresh plumage slightly tipped whitish on tertials and secondaries; tail dark brown, faint white tips when feathers fresh; throat and underparts white; iris dark brown; bill and legs black. Female is very similar to male, but has dark rufous patch on flanks. Juvenile has brownish-black face mask over lores, eye and ear-coverts, crown to lower back grey-brown, finely barred buff, rump and uppertail-coverts buffy white and heavily dark barred, primaries black with white patch, secondaries and wing-coverts edged buff, tail brownish-black, narrowly tipped buff, underparts whitish, dark barring on breast and upper belly, bill blackish grey-brown. **VOICE.** Very noisy; main calls often in chorus, harsh chattering scolding notes and whistles. Notes combined in repeated phrases given simultaneously by 2–6 members of group in duet and chorusing; chorus appears to be initiated by one bird with “cha-cha-raa”, to which another responds with “chit-er-row, chit-er-row”, both calling together. Commonly heard 3-note phrase combines harsh sounds with whistled endings, “zzreele-tzzrulu-tzzreele”. Other calls include low inhaled “chaak...”, “tzzzz”, cackling “ae-ae” and more musical repeated “kech-wa”; alarm a repeated harsh rasping “kerrr-kerrr-kerrr”; begging call a quavering nasal “naaa-aaaa...”. **Habitat.** Open dry habitats such as almost treeless savannas, in shrubby open woodland and cultivated patches. From sea-level near coast of Kenya to 1600 m at S & E edges of highlands.

Food and Feeding. Insects, mainly beetles (Coleoptera) and Orthoptera; regularly also small vertebrates such as lizards, snakes and young birds; will also eat fruit (*Salvadora persica*), and bread and cheese. Solitary or in small groups. Hunts from perch c. 2 m high, from where it dives to ground to capture most of its prey; some prey taken from foliage, but rarely takes aerial prey. Apparent mutualistic association with Red-billed Buffalo Weavers (*Bubalornis niger*) reported in Kenya (Tsavo), where the shrike benefited from the grasshoppers and other insects flushed at ground level by the foraging weavers, and the latter benefited from the shrike’s vigilance and alarm calls. Almost certainly impales prey and maintains food caches.

Breeding. Breeds May–Jun in Somalia, Jan–May, Aug–Oct and Dec in Kenya, and Jan and Jun in Tanzania. Despite close similarity to co-operatively breeding shrikes in visual and vocal displays, and gregarious gatherings, only single pair recorded at nests; each pair holds separate territory, and species congregates in evening in groups of 4–6 individuals. During displays very noisy and conspicuous, frequently waving long tail in all directions, and raising fanned tail over the back. Nest a large open cup made mainly from grass and rootlets, also small twigs and with spider web around the rim, lined with finer material, concealed on horizontal fork or sloping branch 2–3 m from ground in bush or dense tree. Clutch usually 3 eggs, occasionally 4, olive to creamy, variably blotched and spotted dark brown, yellow-brown and purple-brown, markings mainly around larger end; incubation period 13–14 days, nestling period 16–18 days, no information on roles of sexes.

Movements. Resident; wanderers sometimes appear slightly S of regular breeding range in Tanzania, suggesting some movements.

Status and Conservation. Not globally threatened. Generally common in relatively small range. This species’ habitat is probably not at any immediate risk, but survey recommended. Main threats are poisoning during avicide spraying of Red-billed Quelea (*Quelea quelea*) flocks. Kept in captivity, but any adverse effects of trade in this shrike not evaluated. Occurs in several protected areas, e.g. Nairobi National Park, in Kenya, and Tarangire and Mikumi National Parks, in Tanzania.

Bibliography. Brosset (1989), Friedmann (1937), Fry *et al.* (2000), Gadow (1883), Hall & Moreau (1970), Harris & Franklin (2000), Lefranc & Worfolk (1997), Lewis & Pomeroy (1989), Moreau (1972), Olivier (1944), Zimmerman *et al.* (1996).

20. Taita Fiscal

Lanius dorsalis

French: Pie-grièche des Teita **German:** Taitawürger **Spanish:** Alcaudón de los Taita
Other common names: Teita Fiscal, Taita Fiscal Shrike

Taxonomy. *Lanius (Fiscus) dorsalis* Cabanis, 1878, Ndi, Teita, Kenya. Morphology, distribution and vocalizations suggest that this species' closest relative is *L. somalicus*. Monotypic.

Distribution. Extreme SE Sudan, S Ethiopia and S Somalia (except extreme S coastal zone) S to NE Uganda (Kidepo Valley S to Moroto), NE & E Kenya (absent SE coastal strip from Malindi S to Tanzanian border) and NE Tanzania (lowlands of Serengeti plains E to Kilimanjaro).

Descriptive notes. 21 cm; 45–55 g. A medium-sized black-and-white shrike with relatively short tail. Male has top and side of head to upper mantle black, and contrasting pale grey lower mantle, back and rump, whitish on uppertail-coverts, scapulars conspicuously white; upwing black, small white patch near base of primaries; tail black, with white edges and tips; throat and underparts pure white; iris dark brown; bill and legs black. Female resembles male, but at least sometimes has small rufous to chestnut streaks on flank, usually concealed by closed wing. Juvenile has blackish-brown facial mask from lores to ear-coverts, is

greyish-brown with fine black barring above, rump buffy with dark bars, wing feathers dark with pale buff edging and tips, tail brownish-black with whitish edges and tips, underparts dull whitish, bill pale grey-brown. Voice. Little known. Song described as repeated phrases with mix of short whistles, harsh buzzy calls, hollow sounds, and ticking and tinkling notes. Also buzzy notes and whistles combined with double sounds e.g. “tztuptzup”, “wokwok”, “kloplop” and “tudid”; also repeated harsh buzzy “bzzree-bzzree” notes and flute-like whistled calls. Alarm a harsh grating “churr”.

Habitat. Inhabits dry open bush, acacia (*Acacia*) woodland and other dry open woodland, from sea-level to at least 1600 m. Avoids highlands, subhumid and humid areas, as well as extremely arid and sparsely vegetated habitats; thus, ecologically segregated from *L. collaris*, *L. cabanisi* and *L. somalicus*.

Food and Feeding. Little known. Feeds mainly on invertebrates, especially grasshoppers (Orthoptera), beetles (Coleoptera), caterpillars and spiders (Araneae); also takes small vertebrates, including rodents, lizards and small snakes, and possibly also nestlings from Red-billed Quelea (*Quelea quelea*) colonies. Hunts from perches 2–6 m above ground, taking most prey on ground; occasionally gleans from vegetation, and takes aerial prey. Probably impales prey items, but confirmation required.

Breeding. Breeds in May in Somalia and in Jan and Jun in Tanzania; season in Kenya Mar–Jun and Dec–Jan, coinciding with rains. Monogamous; solitary nester, territorial. Nest a thick-walled open cup made from grass and twigs, generally placed in thorn bush or tree. Clutch 3–4 eggs, creamy to pale greyish, with brown and grey spots mostly around larger end. No other information.

Movements. Little known. Regarded as resident, but some local movements reported in Kenya, as well as possible post-breeding movement May–Jul in Somalia. Vagrants recorded W as far as Kericho (SW Kenya), where individual found in atypical moist habitat, and S to Dar es Salaam (Tanzania).

Status and Conservation. Not globally threatened. Widespread and common; less common in extreme S of range. Precise limits of distribution uncertain, especially in N. Population estimated at fewer than 100,000 breeding pairs; trends unknown. Conservation status hardly known, but probably not at any immediate risk. Occurs in several protected areas, including Buffalo Springs National Reserve and Shaba Game Reserve, in Kenya, and Serengeti National Park, in Tanzania.

Bibliography. Ash & Miskell (1998), Britton (1980), Brown & Britton (1980), Dowsett & Dowsett-Lemaire (1993), Friedmann (1937), Fry *et al.* (2000), Fuggles-Couchman & Elliot (1946), Hall & Moreau (1970), Harris, T. (1998), Harris, T. & Franklin (2000), Lack (1985), Lefranc & Worfolk (1997), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1960), Nikolaus (1987), Olivier (1944), Schmidt (1982), Short *et al.* (1990), Stevenson & Fanshawe (2002), Tomlinson (1950), Urban & Brown (1971), Zimmerman *et al.* (1996).

21. Somali Fiscal

Lanius somalicus

French: Pie-grièche de Somalie **German:** Somaliwürger **Spanish:** Alcaudón Somali

Taxonomy. *Lanius somalicus* Hartlaub & Heuglin, 1859, Bender Gam, Ker-Singeli-Somals country, Red Sea, Somalia.

Morphology, distribution and vocalizations suggest that this species' closest relative is *L. dorsalis*. Monotypic.

Distribution. Extreme SE Sudan, Ethiopia (except N & W), Somalia (except SW) and NW Kenya (L. Turkana basin E to Marsabit).

Descriptive notes. 20–21 cm; 48–58 g. A medium-sized black-and-white shrike with relatively short tail. Male has top and side of head to upper mantle jet-black, lower-mantle and back pale grey, scapulars, rump and uppertail-coverts white; upwing black, large white patch near base of primaries, rather broad white tips on secondaries and tertiaries; tail black, outer two feather pairs almost wholly white, other rectrices except central pair tipped white; throat and underparts white; iris dark brown; bill and legs black. Differs from *L. dorsalis* in being slightly slimmer and in having more white in outer tail, wing, scapulars and rump. Female is very like male,

but axillaries brownish-grey (not black). Juvenile has dark brown facial mask from lores to ear-coverts,

top of head and upperparts greyish-brown with very fine darker vermiculations, rump buffish with dark barring, wings dark brown with broad buff edgings and tips, white primary patch, tail dark brown with white sides and tip, whitish below, breast and flanks vermiculated brown. Voice. Song described as a mix of initial atonal buzzes and rather musical short whistles, e.g. “bur-er-er...lit-it-it” or “tchechetcher-br-r-we-weet”. Calls “thring-thring”; alarm said to be a low churring note.

Habitat. Very arid and sparsely vegetated habitats: found in acacia (*Acacia*) short-grass savanna plains, open bushland (*Acacia-Commiphora*), semi-desert savanna with a few small bushes (*Acacia-Chrysopogon*), and sandy or stony almost pure desert. Where sympatric with *L. dorsalis* (e.g. in Kenya and S Ethiopia) prefers more arid habitats with less bush cover than those occupied by latter species. From sea-level to 2000 m in Ethiopia and Somalia; breeds only between 400 m and 1000 m in Kenya.

Food and Feeding. Feeds mainly on large arthropods such as beetles (Coleoptera), grasshoppers (Orthoptera) and mantises (Mantodea); also on small birds and, probably, other small vertebrates. Perches on exposed branches on top or side of trees and bushes, also utilizing artificial elevated features such as telephone wires. Dives down on to prey on ground. Impales prey and regularly maintains caches. Exoskeletal remains and pellets form characteristic litter under favourite bush.

Breeding. Season protracted, taking place during wettest months of year (when food likely to be more abundant); Nov–Feb and Apr–Jul in Somalia (laying earlier on coast than in interior), nests found in Mar, May–Aug and Nov in Ethiopia, and May–Nov in Kenya. Monogamous. Solitary nester; territorial, particularly aggressive near nest, and known to attack any species up to size of a raven (*Corvus*). Nest an open shallow cup made from thorn twigs, rootlets and silky fibrous materials, external diameter 11.4 cm, height 6.4 cm, internal diameter 6.4 cm, placed up to 2 m above ground (but generally lower) in small bush or in centre of thorn tree. Clutch 4 eggs, less often 3, mostly creamy but sometimes greenish-white, with pale brown spots and ash-grey underlying marks at either end. No other information.

Movements. Resident. Some possible local movements; two individuals found at Djibouti in Mar and, in S, wanderers recorded in Kenya (Baringo, Wamba, Merti and Isolo districts) as far S as N periphery of the highlands and sometimes in atypically moist areas.

Status and Conservation. Not globally threatened. Common in Somalia; uncommon to frequent in Ethiopia; uncommon and local in Kenya. Status in SE Sudan uncertain: rare or under-recorded in this area, and breeding not proved. This species seems to be frequent in much of its range, and is believed not to have declined to any significant extent in recent years. Habitat probably not threatened. Present in Awash National Park, in Ethiopia; present in half of the 24 Important Bird Areas (IBAs) in Somalia, in four out of 70 IBAs in Ethiopia and in only two IBAs in Kenya, although only some of these areas are totally or partially protected.

Bibliography. Archer & Godman (1961), Ash & Miskell (1983, 1998), Britton (1980), Brown & Britton (1980), Fishpool & Evans (2001), Friedmann (1937), Fry *et al.* (2000), Grasseau (2004), Hall & Moreau (1970), Harris & Franklin (2000), Lefranc & Worfolk (1997), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1960), Nikolaus (1987), Stevenson & Fanshawe (2002), Welch & Welch (1984), Zimmerman *et al.* (1996).

22. Mackinnon's Shrike

Lanius mackinnoni

French: Pie-grièche de Mackinnon **Spanish:** Alcaudón de Mackinnon

German: Mackinnonwürger

Other common names: Mackinnon's Fiscal/Grey Shrike

Taxonomy. *Lanius mackinnoni* Sharpe, 1891, Kikuyu (= Bugemaia, Kavirondo), Kenya.

Affiliations unclear; may be closely related to *L. collaris*. W populations named as geographical race *zenkerianus* (described from Younde, in S Cameroon), but considered inseparable from birds elsewhere in species' range. Monotypic.

Distribution. SE Nigeria (Obodu Plateau) and SW Cameroon S to S PR Congo and NW Angola (S at least as far as Quiculungo), and N DR Congo E to extreme W Kenya and S to SW Uganda, W Rwanda, Burundi and NW & N Tanzania.

Descriptive notes. 20–21 cm; 35.6–37 g. A fairly large pied shrike with rather long, graduated tail. Male has black facial mask from lores back to ear-coverts, contrasting white lower forehead and conspicuous supercilium; crown to nape and mantle sooty grey, back, rump and uppertail-coverts paler, scapulars contrastingly white; upwing black, tail black with broad white feather tips; white below, underparts variably washed pale buff; iris dark brown; bill and legs black. Female is similar to male, but has distinctive patch of chestnut on flanks (usually concealed). Juvenile has facial mask dark brown, supercilium whitish, top of head

and upperparts greyish-brown with narrow dark barring, whitish scapulars tipped buff, underparts whitish with variable buff wash and vermiculated brownish. Voice. Song a mix of hoarse “chruu” calls and intense and diverse notes like those of a warbler (Sylviidae), including much mimicry. Rest of repertoire consists of harsh sounds and prolonged whistles; alarm call a rough chatter or rattling “ra-a-a...”, “zik-zik...” or “k-k-k-k-k-k-k-k”, but reported also as a protracted whistle.

Habitat. Primarily savanna, and forest edges and clearings, locally also cultivations, secondary growth and open plantations; largely avoids dense forest. From almost sea-level, e.g. in Gabon, to up to 2200 m in mountain areas of Kenya and E DR Congo. Breeding range restricted to tropical rainy climate.

Food and Feeding. Mainly insects, particularly Orthoptera, beetles (Coleoptera), bugs (Hemiptera), winged termites (Isoptera), ants (Formicidae) and the like; small vertebrates taken regularly include geckos (Gekkonidae), frogs and small passerines. Hunts from prominent perch 2–5 m up, infrequently higher; takes prey mainly from ground, less often in air or from foliage. Follows ant swarms. Impales prey items, including small nestlings of other birds; maintains food caches.

Breeding. Breeds Sept–Apr in Cameroon, and elsewhere in W of range (e.g. Gabon) display, copulation and occupied nests observed between Aug and Apr, and fledglings being fed by adults at end of May (Angola); in E range breeds Feb–Aug, centred on long rain (with peaks before and at start of rains); two broods apparently regular. Nest a rather bulky open cup made from coarse dry grass,

On following pages: 23. Common Fiscal (*Lanius collaris*); 24. Newton's Fiscal (*Lanius newtoni*); 25. Uhehe Fiscal (*Lanius marwitszi*); 26. Woodchat Shrike (*Lanius senator*); 27. Masked Shrike (*Lanius nubicus*); 28. Yellow-billed Shrike (*Corvinella corvina*); 29. Magpie Shrike (*Corvinella melanoleuca*); 30. Southern White-crowned Shrike (*Eurocephalus anguitimens*); 31. Northern White-crowned Shrike (*Eurocephalus ruppelli*).

bark shreds and plant stalks, lined with finer fibres, placed 1–3 m above ground in thorny bush or small tree; territory size 1–6 ha, depending on preponderance of bushes. Clutch 2 eggs, sometimes 3, buffish, with yellowish-brown, purple and grey spots and speckles; incubation possibly by both sexes; no information on duration of incubation and nesting periods.

Movements. Resident; juveniles probably undertake local movements.

Status and Conservation. Not globally threatened. Poorly known, with relatively little information on status. Locally not uncommon in W of range; locally common to uncommon in E. Effects of deforestation on this species not known, but possibly beneficial in producing additional secondary growth suitable for this shrike.

Bibliography. Borrow & Demei (2001), Chapin (1954), Dean (2000), Fry *et al.* (2000), Hall & Moreau (1970), Harris & Franklin (2000), Lefranc & Worfolk (1997), Lewis & Pomeroy (1989), Zimmerman *et al.* (1996).

23. Common Fiscal

Lanius collaris

French: Pie-grièche fiscale **German:** Fiskalwürger **Spanish:** Alcaudón Fiscal
Other common names: (Common) Fiscal Shrike, Long-tailed Pied Shrike; Latakoo/South-west African Fiscal (*subcoronatus*)

Taxonomy. *Lanius collaris* Linnaeus, 1766, Cape of Good Hope, South Africa. Forms a superspecies with *L. newtoni* and *L. marwizi*, and all three formerly treated as conspecific. Differences between N races and S races in juvenile plumage, extent of sexual plumage dimorphism, visual displays, and possibly vocalizations suggest that two different species may be involved; further study required, especially involving molecular genetics; possible vocal differences appear minimal and perhaps local. Races intergrade in many areas, making taxonomic and geographical delimitation of forms sometimes uncertain. Race *aridicolus* closely allied to and often merged with *subcoronatus*, but geographically isolated in coastal dunes of Namib region. Other proposed races are *predator* (from near Ingwavuma, in NE KwaZulu-Natal), most often subsumed in nominate but sometimes considered a synonym of *pyrrhostictus*; *vigilans* (from near Kloof, in E Natal), synonymized with nominate; and *dominator* (from Muchinga Range, in SC Zambia), merged with *capelli*. Seven subspecies currently recognized.

Subspecies and Distribution.
L. c. smithii (Fraser, 1843) – S Mauritania (rare), S Mali (rare) and from S Guinea, Sierra Leone and Liberia E to Central African Republic, N PR Congo, SW Sudan and W Uganda.
L. c. humeralis Stanley, 1814 – C Eritrea, C & S Ethiopia, SE Sudan, E Uganda, W Kenya, Tanzania, N Malawi and N Mozambique; probably also NE Zambia.
L. c. capelli (Bocage, 1879) – S Gabon and S PR Congo E to S DR Congo, extreme SW Uganda, Rwanda and Burundi, and S to Angola (except S), Zambia and N Botswana, possibly also extreme SW Tanzania and extreme NE Namibia.
L. c. aridicolus Clancey, 1955 – SW Angola and NW Namibia (dune-fog zone of Namib Desert).
L. c. subcoronatus A. Smith, 1841 – extreme SE Angola, Namibia (excluding coastal NW and extreme S), Botswana, SW Zimbabwe and N South Africa (S to NW Northern Cape and C Free State).
L. c. pyrrhostictus Holub & Pelzeln, 1882 – extreme NE Botswana (around Basuto), S Zimbabwe (S of Harare), NE & E South Africa (Limpopo and Mpumalanga) and SW Mozambique (almost restricted to Gaza province).
L. c. collaris Linnaeus, 1766 – extreme S Namibia, S, C & E South Africa, Swaziland, Lesotho and extreme S Mozambique (Maputo).

Descriptive notes. 21–23 cm; 25–58 g. A medium-large black-and-white shrike with long, thin, graduated tail. Male nominate race has top and side of head to mantle and back black, prominent white scapulars (can be fluffed up or concealed), grey rump and uppertail-coverts; upperwing black, white patch near base of primaries (white scapulars and primary patch prominent in flight); tail black, outermost feather pair almost completely white; underparts greyish-white to grey, often whiter on chin and throat and again from central belly to undertail-coverts, breast to belly faintly vermiculated with pale greyish, underside of

flight-feathers shiny dark slate; iris dark brown; bill and legs black. Female is usually duller than male, often with some rufous on flanks. Juvenile has dark brown facial mask from lores to ear-coverts, dull brownish-grey above, finely to heavily barred buffy, scapulars buffy to brownish-white with blackish margins, wings dark brown, buffy tips on tertials and coverts, buff-white below, vermiculated greyish-brown (bars more widely spaced and less definite on belly and slightly rufous flanks), bill dark with pinkish base. Races differ mainly in intensity of colour on upperparts, presence or absence of white supercilium, freckling on breast, degree of sexual dimorphism and amount of white in tail (subpopulations of nominate exhibit significant differences along an altitudinal gradient in morphological features, skeletal characters and physiology, with largest in cooler and less humid areas): *subcoronatus* is similar to nominate but with narrow white supercilium, whitish uppertail-coverts, female has distinct chestnut flank patch; *aridicolus* is paler and greyer above than previous, more white in tail, underparts purer silky white; *humeralis* has dull black upperparts and dull white underparts, outer tail feathers completely white, chestnut flank patch of female generally well marked, juvenile more rufous and with dense blackish barring; *pyrrhostictus* is similar to previous, but upperparts slightly greyer, underparts tinged grey, female with chestnut patch on flank; *capelli* also is similar to *humeralis*, but extent of white on tail variable. Outer rectrices often black at base, chestnut flank patch of female greatly reduced or absent; *smithii* has glossy black upperparts with bluish gloss, grey rump, underparts clear white, female's rufous flank patch small or lacking, juvenile has rufous-brown upperparts barred dark. **VOICE.** Song, by both sexes throughout year, variable, consists of a full-throated, disjointed medley of short clear whistles, unmusical trills and warbles, and imitations of other birds, interspersed with harsh grating notes, also 3 low buzzing notes followed by 4 double whistles, as “zzzz-zzzz-zzzz tiss-weeo, tiss-weeo, tiss-weeo” (attraction call a variant of this); juvenile starts to produce discordant warbling subsong a few days after leaving nest. Female utters “naaa” call to solicit copulation. Alarm a loud grating “ghreee, ghreee, ghreee”; territorial call, used also as alarm and part of song, a discordant “djaaaa-djaaaa” or “djaaaa-dju”. Nestlings beg with insistent rasping “cheee, cheee” and give screeching alarm calls.

Habitat. Open areas with short grass and scattered shrubs, including woodland and open savanna, often with acacias (*Acacia*), also semi-desert, coastal thickets, bushy margins of marshes, as well as miombo (*Brachystegia*) shrubland with scattered trees. Relatively scarce in arid woodland and alpine grasslands. Has adapted to wide variety of artificial habitats, e.g. common around edges of

plantations, farms, around urban gardens and parks, and along roadsides with telephone lines and fences. Also in recently burnt or overgrazed wooded savanna grassland, forest clearings and well-cleared land. From near sea-level (race *aridicolus*) to up to 3350 m; at least in E Africa, generally more common in highlands than at lower elevations.

Food and Feeding. Wide food spectrum includes mainly invertebrates, fewer vertebrates; occasionally seeds. Invertebrates include, among others, crickets, grasshoppers and locusts (Orthoptera), mantids (Mantodea), beetles (Coleoptera), butterflies and moths (Lepidoptera), damselflies (Zygoptera), termites (Isoptera) and ants (Formicidae), spiders (Araneae), millipedes (Diplopoda) and snails (*Achatina zebra* and *Natalina*). Vertebrate prey recorded include e.g. small frogs and tadpoles, reptiles (snakes, skinks, chameleons and other lizards), small rodents, birds (adults, fledglings and nestlings) and bats, including Cape serotine (*Eptesicus capensis*) and Kuhl's pipistrelle (*Pipistrellus kuhli*). Prey up to 18 cm long recorded. Occasionally takes seeds, and observed to take food scraps from dog bowls. Sit-and-wait predator, hunting from conspicuous perch 1–10 m above ground. Usually seizes prey from ground, but occasionally hawks insects in air, gleans insects from foliage, or hovers above prey on ground; will also plunge-dive to catch tadpoles, and has been reported as scavenging food items. Small prey usually consumed on the ground. Larger items more often carried to perch, where the shrike kills its victim by crushing it in the bill or beating it hard against perch. Large prey sometimes held in one foot torn apart with the bill, or impaled on thorn, wood splinter, flowerhead spike or barbed wire. Impaled items may accumulate in larders (regularly recorded in Ghana and Kenya, less in S of range).

Breeding. Breeds mainly in rainy season when food abundant (especially in relatively arid areas), mostly Feb–Aug in W Africa, Aug–Nov in Angola, Apr–Jul in NE Africa, and in most months in E Africa; in S of range, Aug–Jan in Namibia, May–Dec in Botswana, Apr and Jun–Jan in Zimbabwe; and in South Africa, May and Jul–Dec in Western Cape, Apr and Jul–Jan in Eastern Cape, Jun–Jan in KwaZulu-Natal; often two or three broods. Monogamous; solitary, territorial nester. Nest built by both sexes, a deep, bulky, thick-walled cup made from wide range of materials, including twigs, grass, leafy herbs, flowerheads, bark fibres, moss, spider webs and cocoons, feathers, and artificial material (e.g. string, pieces of paper, rags), lined with rootlets, woolly plant down and fine grass inflorescences, mean external diameter 13 cm, height 9.5 cm, internal diameter 7.5 cm and depth 5 cm; placed mostly 0.6–6 m (exceptionally to 15 m, average 3 m) above ground in small, often thorny tree or shrub, occasionally on man-made structure; nest sometimes used for successive broods. Clutch 1–4 (exceptionally 6) eggs, pale cream to greenish, with brown, grey and dull yellow-olive spots mainly in ring around larger end; incubation by female, occasionally assisted by male, from last or penultimate egg, period 12–16.5 days, normally 14–15 days; sometimes marked size disparity among siblings, chicks brooded by female, fed by both sexes, nestling period usually 17–21 days; fledglings independent c. 5–7 weeks after leaving nest, remain in parental territory for up to c. 7 months. Nests parasitized by Jacobin Cuckoo (*Clamator jacobinus*), Diederik Cuckoo (*Chrysococcyx caprius*) and African Cuckoo (*Cuculus gularis*), possibly also by Red-chested Cuckoo (*Cuculus solitarius*) but evidence inadequate. Eggs sometimes preyed on by common egg-eating snake (*Dasypeltis scabra*); tropical nest fly (*Passeromyia heterochaeta*) causes myiasis in nestlings, which is sometimes fatal.

Movements. Mainly resident and sedentary throughout most of range. No large-scale movements reported, but some degree of local movement may occur. Partial migrant in driest parts of range; in Botswana predominantly a winter visitor. Occasional appearance of *subcoronatus* in E South Africa (near Pretoria and Johannesburg).

Status and Conservation. Not globally threatened. Common to abundant in most of range; locally uncommon, and rare in extreme NW parts. Has become more numerous as a result of urban settlement and development. Common bird in residential suburbs and even city centres in E Africa, with densities up to 5.4 pairs/10 ha. Has spread in S Africa into open areas where overhead lines and wires provide lookout perches; low reporting rates in Transkei and Lesotho, however, indicate a certain degree of sensitivity to different types of land use.

24. Newton's Fiscal

Lanius newtoni

French: Pie-grièche de Sao Tomé **Spanish:** Alcaudón de Santo Tomé
German: Sao-Tomé-Würger
Other common names: São Tomé Fiscal

Taxonomy. *Lanius (Fiscus) Newtoni* Bocage, 1891, São Tomé. Forms a superspecies with *L. collaris* and *L. marwizi*, and all three formerly treated as conspecific. Monotypic.

Distribution. Island of São Tomé, in Gulf of Guinea.

Descriptive notes. 19–21 cm; one female 22.4 g. A medium-sized pied shrike with longish, graduated tail; comparatively small and weak bill with very small hook at tip of upper mandible. Has top and side of head black (glossy at side), upperparts glossy black, scapulars yellowish; upperwing glossy black, tertials distinctly white-tipped, very small white patch on primaries (sometimes lacking); tail black, three outer pairs of rectrices edged white towards tips; throat and underparts white (museum specimens), but on at least some live individuals pale yellow or washed yellowish; iris dark brown; bill black; legs dark brown or black.

Distinguished from very similar *L. collaris* by yellowish underparts (when present), less white in tail, smaller bill, often lack of white primary patch. Sexes apparently similar. Juvenile is poorly known, apparently brown and narrowly barred above, tawny-yellow to orangey with fine vermiculations below, bill horn-brown (not black). **VOICE.** Little information available. Supposed territorial call a loud, rather nasal repeated “juurt-juurt-juurt...” or “tuurt-tuurt...”; or a series of far-carrying well-separated fluted “tiu” notes repeated several times. Presumed alarm a rapidly delivered, harsh, rasping “kerkerkerkerker...” or “kikikikikiki...” and quickly repeated harsh “tzk” or “tsink”.

Habitat. Undisturbed lowland and middle-altitude primary rainforest, mainly under closed canopy, with little or no undergrowth. Most observations have been made in virgin forest below c. 700 m, with some exceptional records from 1060 m. The only true forest-dwelling member of the genus.

Food and Feeding. Little information. Insectivorous, seems to feed on small beetles (Coleoptera) and flying insects. Believed not to prey on small vertebrates (bill too small and weak). Apparently a species of the middle to lower storey, and curiously difficult to see. Most individuals observed were skulking in low bushes, sometimes more in the open; one individual recorded as foraging on boulders in a stream, another as taking small beetles from the ground; one pair observed 5 m below canopy in dense primary forest.

Breeding. Little information. Singing heard in Dec–Jan and Aug; two males in breeding condition in Nov–Dec, and two females showing traces of juvenile plumage in same months. Observation of different pairs and family groups suggests that it is monogamous. No other information.

Movements. Presumably sedentary.

Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species: present in São Tomé EBA. Rare. First discovered in 1888, and 13 specimens collected in 1928; thereafter, not seen again for more than 60 years and was assumed to have become extinct. In 1990, however, a single individual was located in SW part of São Tomé, near the source of R Xufexufe; since mid-1990s has been seen with some regularity, mostly in Xufexufe catchment, but total population thought probably to number fewer than 50 individuals. Reasons for this species' rarity not known but, unlike its congeners, it inhabits forest, much of which on São Tomé has been damaged or destroyed. During Portuguese administration of the island most of the cleared areas were used for growing cocoa and coffee; in more recent years, however, land privatization has resulted in a huge increase in number of small farms, and consequent removal of large numbers of trees. Possible effects of any introduced predators, such as black rat (*Rattus rattus*) and mona monkey (*Cercopithecus mona*), on the shrike's population require investigation.

Bibliography. Anon. (2007m), Atkinson, Dutton *et al.* (1994), Atkinson, Peet & Alexander (1991), Borrow & Demei (2001), Butchart & Stattersfield (2004), Christy & Clarke (1998), Collar & Stuart (1985), Collar *et al.* (1994), Harris & Arnott (1988), Harris & Franklin (2000), Hirschfeld (2007), Jones & Tye (2006), Lefranc & Worfolk (1997), de Naurois (1994), Peet & Atkinson (1994), Sargeant (1994), Stattersfield & Capper (2000).

25. Uhehe Fiscal

Lanius marwitszi

French: Pie-grièche de Tanzanie **German:** Reichenowwürger **Spanish:** Alcaudón Tanzano
Other common names: Uhehe Shrike

Taxonomy. *Lanius marwitszi* Reichenow, 1901, Ngomingi, Uhehe (Iringa District), Tanzania. Forms a superspecies with *L. collaris* and *L. newtoni*, and all three formerly treated as conspecific. Inhabits highland areas, thus ecologically segregated from *L. collaris* and apparently not interbreeding with it (and very little intergradation with local race *humeralis* of latter), but intermediates sometimes mentioned; further morphological and genetic study required. Monotypic.

Distribution. Highlands from NE to SC Tanzania (Mpwawpa and Ukagurus S to Njombe, Mt Rungwe and Tukuyu).

Descriptive notes. 20–23 cm. A medium-sized, slim, pied shrike with relatively long and graduated tail. Male has distinct white supercilium covering upper lores and merging into white frontal band above bill; crown and nape to back dull black, prominently white scapulars, dark grey rump and uppertail-coverts; upperside dull black, small white patch near base of primaries; tail black, outer pair of feathers almost entirely white, others except central pair with white spots at tip; throat and underparts off-white, sometimes buffish wash, undertail wholly white; iris dark brown; bill and legs black. Sexes probably similar, female

seems always to lack rufous patch on flank (present in *L. collaris*). Juvenile has traces of whitish supercilium, is dark brownish-grey above, finely to heavily barred buffish, rump slightly lighter in colour, scapulars buffy to brownish-white, wings dark brown, buffy tips on tertials and coverts, underparts buffy white and heavily barred greyish-brown, bill dark with pink base. Voice. Hardly known; apparently rather silent. Supposed to be similar to that of *L. collaris*.

Habitat. Bush and savanna country, grassland, clearings and farms; above 1500 m, to at least 2900 m. Perhaps generally in more natural habitats than those occupied by *L. collaris*.

Food and Feeding. No details. Probably mainly invertebrates.

Breeding. No information.

Movements. No information, but local altitudinal movements appear possible.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Very poorly known species. Seems to be locally common. Estimated population fewer than 10,000 breeding pairs. Trends and conservation status not known. Further study on taxonomy and conservation status needed.

Bibliography. Britton (1980), Friedmann & Loveridge (1937), Fry *et al.* (2000), Hall & Moreau (1970), Harris, T. (1998), Harris, T. & Franklin (2000), Lefranc & Worfolk (1997), Mackworth-Præd & Grant (1960), Stevenson & Fanshawe (2002).

26. Woodchat Shrike

Lanius senator

French: Pie-grièche à tête rousse **German:** Rotkopfwürger **Spanish:** Alcaudón Común
Other common names: Woodchat; Eastern Woodchat Shrike (*niloticus*)

Taxonomy. *Lanius Senator* Linnaeus, 1758, “Indiis”; error = Rhine valley, Germany. Geographical variation partly clinal, amount of white at tail base increasing from W to E. Validity of race *rutilans* has been questioned; possibly better merged with nominate. Proposed race *hensii* (from Sicily) synonymized with nominate. Four subspecies generally recognized.

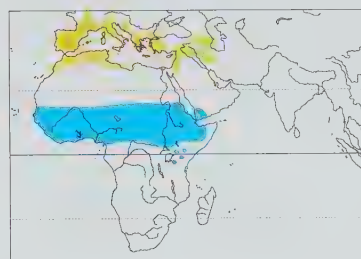

Subspecies and Distribution.

L. s. senator Linnaeus, 1758 – breeds patchily from N Spain and C & S France (mainly Languedoc–Roussillon and Côte d’Azur) E to Sicily and Greece (including Corfu, Crete and most bigger islands in Aegean Sea), coastal Balkans E to S Bulgaria and W Turkey, and also locally and irregularly in Switzerland, SW Germany (upper Rhine Valley, foothills of Swabian Mts, Saarland), SE Poland and SW Slovakia; non-breeding W & C Africa.

L. s. rutilans Temminck, 1839 – breeds Iberian Peninsula (except N Spain) and NW Africa, from Moroccan Atlantic coast E to NW & NE Libya, S to S slopes of Anti-Atlas and Middle and High Atlas; non-breeding W Africa.

L. s. badius Hartlaub, 1854 – breeds islands in W Mediterranean (Balearics, Capraia, Corsica, Sardinia); non-breeding W Africa.

L. s. niloticus (Bonaparte, 1853) – breeds Cyprus, S & E Turkey, Levant and N Iraq (Kurdistan) E to Iran (Zagros Mts; possibly also SE to Baluchistan and in Elburz Mts); non-breeding E Africa and SW Arabia.

Descriptive notes. 18–19 cm; 21–59 g. A medium-sized, rather bulky-looking shrike with distinctive plumage pattern. Male nominate race has black forehead and facial mask to ear-coverts and rear neck side, short whitish supercilium (often inconspicuous); crown to upper mantle rufous, scapulars white, lower mantle and back black, rump and uppertail-coverts white; upperside dark brown, broad white patch near base of primaries; tail black, all except central feather pair tipped white, outermost pair white with some black basally on inner web (occasionally wholly white); throat and underparts white, in fresh plumage

a creamy-buff wash on underparts; iris brown or dark brown; bill black; legs blackish. Female is duller than male, white patch over bill extends back to eye. Juvenile has lores mixed brown and whitish, ear-coverts brownish, forehead to back rufous-buff (becoming greyish) with dark brown and white barring, scapulars whitish, rump pale rufous-buff with dark barring, wing patch buff, wing-coverts edged light buffish, outer rectrices buff-white, underparts whitish with grey-brown crescent markings, bill dark grey, flesh-grey lower mandible. Race *rutilans* is smaller than nominate; *badius* differs distinctly from nominate in having narrower black forehead, only vestigial white area on base of primaries (often hidden); *niloticus* has white of rump extending well on to tail base, white primary patch distinctly broader than in nominate. Voice. Contact calls described as “kwikwik” or “pitquür”, and alarm as “geg”, “tschek” or harsher “kreck”, often in long series; in conflicts between males a long and strong “drirdr” uttered, of similar function is a soft “grüg”; in aggression very quickly repeated “tr-tr-tr-tr-trtrtr...” sounds. Song a continuous warble with mixture of harsh notes and sparsely interspersed imitations of other birds’ songs, and once a European tree-frog (*Hyla arborea*) imitated; in contrast to congeners, song believed to have also some territorial function; female also sings, sometimes in synchrony with male song to form duets.

Habitat. Generally in semi-open areas with bushes and well-spaced trees, such as open woodland, old orchards, olive (*Olea*) groves, gardens, and parks or hedgerows with large thorny bushes; in SE extending to edge of steppe and desert. Open pine (*Pinus*) forest preferred in Greece. In many areas occurs commonly in cultivated country with trees; in N of range a typical bird of old traditional orchards, particularly when sheep or cattle present. Three habitat elements necessary: shrub-like or arboreal cover, open ground offering rich supply of large insects, and perches with commanding view of area. Normally below 1000 m, but in N Israel (Mt Hermon) breeding proved at 1650 m, and in Spain and NW Africa favours holm oak (*Quercus ilex*) and cork oak (*Quercus suber*) to at least 2000 m, although only to 1500 m in Pyrenees. In African winter quarters, found in dry acacia (*Acacia*) savanna, but structure of these light woodlands often resembles that of traditional orchards inhabited in breeding area.

Food and Feeding. Almost exclusively insectivorous, with preference mostly for larger insects such as beetles (of families Carabidae and Scarabaeidae), Orthoptera and caterpillars, also spiders (Araneae); average body length of prey 15.7 mm. Small vertebrates such as lizards, small mammals and birds only occasionally caught. Total of 518 prey items from Georgia consisted of 69 invertebrate species: of these, 159 items from adults (May–Jun) comprised 44.6% beetles, 32.7% Orthoptera, 17.6% Hymenoptera (of which 10.7% ants), 1.9% arachnids and 1.3% snails; 359 prey items from nestlings in same area and at same time comprised 52.9% Orthoptera, 18.4% Hymenoptera (18.1% ants), 17.3% beetles, 8.1% snails, 2% arachnids and 1.1% Hemiptera. Perches on exposed lookout, from which it drops or glides down on to ground prey or makes sallying flights after aerial insects. Impaling of prey recorded only seldom.

Breeding. Laying early May to end Jun in C Europe, earlier, from Apr, in N Africa and from Mar in Israel; two broods usually in S (N Africa and Israel), but exceptional in Europe. Monogamous. Solitary and territorial; nests sometimes more clustered, but tendency to form groups less pronounced than in *L. minor*. Nest built by both sexes, a compact open cup made from twigs and roots and other plant material (including green), lined with rootlets, hair, wool, moss, lichen and spider web, placed mostly on lateral branch of tree, often fruit tree or oak, pine or poplar (*Populus*), 1–20 m above ground but mainly low (mean 4–5 m in C Europe), and in Mediterranean region often low down in dense bush; looks very much like nest of *L. minor* but is stronger, not so loosely built, and generally closer to ground; average territory size 8 ha in SW Germany, 1.5 ha in Georgia. Clutch 4–8 eggs, mean 4.9 in C Europe, 7-egg clutches much more frequent (34%) in Armenia (race *niloticus*) than in W Europe (1–5%), pale green to olive-green, sandy or greyish-yellow, more rarely reddish-yellow or brown, with brown to pale olive speckles concentrated in circle at broad end; replacements (smaller than first clutches) frequent to mid-Jul; incubation by female, fed on nest by male, period 14–16 days; chicks brooded by female, fed by both sexes, nestling period normally 15–18 days, but from 12 days onwards chicks sometimes jump from nest if disturbed; juveniles fed by parents for up to c. 6 weeks after fledging. Breeding success relatively low: of 553 eggs monitored in 112 nests in C Europe, 68.9% hatched, 53.8% reached 7–9 days, and estimated 42% produced fledged young.

Movements. Migratory, wintering in vast belt of sub-Saharan Africa N of equator, and in small numbers in S Arabia. Races have different winter quarters: nominate found from S Mauritania E to Darfur region of Sudan, S to NE DR Congo and Uganda; *niloticus* occurs from Sudan E to Eritrea and SW Arabia; *badius* appears to be confined mainly to S part of W Africa, and *rutilans* probably likewise. Leaves European breeding grounds mostly second half Aug or beginning Sept, adults before juveniles, movement probably on broad front in S to SW direction; arrives in non-breeding quarters Aug–Oct, mainly Sept. Departure from winter quarters protracted, Feb–May; passage of nominate race through Mediterranean area late Mar to early Jun, with main arrival on N breeding grounds around beginning May; E race *niloticus* appears in Israel between end Jan and mid-Feb, much earlier than nominate (which represents c. 10% of country’s total numbers). Some W populations may make loop migration, as recorded more frequently and in larger numbers in E Mediterranean in spring than in autumn. Annual vagrant NW to Britain and Ireland, especially May–Jun; rare in Norway and Sweden.

Status and Conservation. Not globally threatened. Locally common; rare in N parts of range. Majority of European population inhabits Mediterranean region, where Iberian Peninsula may hold over 600,000 breeding pairs, representing more than 70% of total European population. Decreasing trends reported in most of Europe, and now very local or extinct in N & C Europe (Germany,

Poland, Czech Republic, Slovakia, Hungary, Austria, etc.), where last breeding confirmed in 1980s–1990s or where insignificant remnant populations remain. Range contraction towards SW & SE combined with decline in numbers in most European countries evidently part of longer-term trend apparent since middle of 19th century and especially 1970–1980; numbers also decreased during that time in strongholds of France and Spain; in 19th century breeding occurred in old parks in centre of Paris, and in middle of 20th century still bred in cemeteries in Slovakian towns and villages. Protected in most countries; in some listed as “highly endangered”, in others regarded as “vulnerable” or “endangered”. Loss and degradation of habitat through agricultural intensification, afforestation, and large fires are main threats. Traditional management of pastoral woodland, old orchards and Mediterranean scrub, reduced use of insecticides and the prevention of hunting are among the required conservation measures.

27. Masked Shrike

Lanius nubicus

French: Pie-grièche masquée **German:** Maskenwürger **Spanish:** Alcaudón Nubico
Other common names: Nubian Shrike

Taxonomy. *Lanius nubicus* M. H. C. Lichtenstein, 1823, Nubia. Affiliations uncertain, possibly related to some Palearctic brown shrikes and some African fiscal shrikes. Monotypic.

Distribution. Breeds from Balkan Peninsula and Asia Minor S to Levant, including Cyprus, also in N Iraq and W Iran (Zagros Mts); range limits uncertain, possibly includes S Turkmenistan and NW Afghanistan. Non-breeding in sub-Saharan Africa and SW Arabia.

Descriptive notes. 17–18.5 cm; 14.5–30 g (usually c. 20–23 g). Distinctive smallish, rather slim shrike with small bill and proportionately very long and narrow tail. Male has white on forehead and extending behind eye as prominent white supercilium; crown, ear-coverts and nape to upperparts, upperwing and tail glossy black; scapulars white, large white patch at base of primaries, outer two pairs of rectrices almost wholly white; throat, neck sides and underparts white, contrasting orange on breast and flanks; iris brown or dark brown; bill black, palate light pink; legs black or dark brown. Female is similar to male but duller,

dark colour on head dark grey to brownish-black or dull black, orange colour below less intense, bill rather dark brown or plumbeous black. Juvenile is grey-brown above and off-white below, heavily vermiculated all over, with large white primary patch, lacks contrasting head pattern of adults, thus facial mask brown, lower forehead and supercilium whitish; first-winter similar to female but lacks rufous below, bill and legs greyer. Voice. Similar to that of congeners. Calls include short repeated harsh “tsr” or “tztz”, “krret” and “shek” combined with clearer whistles; alarm rattling sounds such as “krrrr” or “krrrt”, sometimes extended to disyllabic “krrrr-krrrr”; repeated hoarse “khir” note and low “rad” also recorded. Begging calls of juveniles range from “scirp-scirp...” to a more churring “skerr-skerr...”. Song rather soft and short compared with those of congeners, and without mimicry, but full of warbles and chatters, somewhat reminiscent of song elements of *Hippoboscidae* warblers. Bill-snapping recorded.

Habitat. Favours natural open woodland with bushes and glades, and fond of big isolated trees. Nests in variety of light deciduous (predominantly), coniferous and mixed forests; also in maquis and maquis-like vegetation. Usually absent from open areas or those near human habitation, but occurs locally in cultivated land dotted with old trees, citrus and olive (*Olea*) groves, orchards, small fields with tall hedges and many trees, vineyards, gardens, and poplar (*Populus*) plantations. Usually in more densely vegetated habitat than other shrikes breeding within same range. Lowland and hilly country, mostly below 1000 m; on some well-exposed mountain slopes can be found at up to 1500 m (Mt Hermon, in N Israel), 1800 m (Zagros Mts, in W Iran), and even to 2000 m (Aladag, in E Turkey). During migration and on African non-breeding grounds, again prefers areas with rather high tree cover; typical habitat in NE Africa is hot acacia (*Acacia*) country, but found also in riverine woodland, Sahel thorn-scrub near streams, and sometimes in open, relatively tall introduced eucalypt (*Eucalyptus*) plantations. Recorded also in gardens and in holiday resorts well provided with trees, especially on passage.

Food and Feeding. Main prey insects; other arthropods and small vertebrates also taken. Among insects, it prefers Orthoptera species, including crickets (Gryllidae) and especially bush-crickets (Tettigoniidae) and grasshoppers (Acrididae), and also beetles (Coleoptera); other insects recorded as prey include dragonflies (Odonata), moths (Lepidoptera, including caterpillars) and ants (Formicidae). During Jun–Jul, consumes large numbers of the bush-cricket *Poecilimon thoracicus* in S Bulgaria. Small vertebrates such as lizards and small passerines (including nestlings) taken occasionally; exhausted migrant birds, e.g. Lesser Whitethroat (*Sylvia curruca*) and even a Little Swift (*Apus affinis*), occasionally caught while on passage. Sit-and-wait foraging technique commonly employed, using less exposed lookouts than those preferred by other shrikes; hunting perches mostly branches of trees or bushes, usually 3–8 m (range 1–15 m) above ground. Dives to ground to capture prey; sometimes catches flying insects, pursuing them in manner of a flycatcher (Muscicapidae), less frequently gleans items from foliage; may hover briefly before taking prey from ground or foliage. Can be quite confiding, taking prey at a human observer’s feet or even closely following a gardener and taking flushed insects. Regularly impales prey.

Breeding. Laying early Apr to mid-Jun, with peak in most areas during first half May, replacement clutches Jun–Jul; starts c. 1 month later in mountainous areas than in those near sea-level (Cyprus, Turkey); two broods probably normal in at least part of range. Monogamous. Solitary, territorial breeder; sometimes loose concentrations locally in favourable habitats, and sometimes pairs quite close together, e.g. two nests 40 m apart in open downy oak (*Quercus pubescens*) forest in S Bulgaria. Nest built by both sexes, sometimes male more active than female; a relatively small open

cup (mean dry weight of 12 nests 20.4 g) very carefully constructed from rootlets, twigs, plant down, plant stems and moss, lined with wool, hair or man-made materials, decorated externally with lichen (more or less camouflaged), placed usually 0.95–12 m above ground (mean 6.5 m for 29 nests in S Bulgaria) against trunk in fork or on lateral branch of tree, sometimes in dense (often thorny) bush; territory appears to be small, under 1 ha to 5 ha. Clutch 3–7 eggs (rarely 8), mostly 4–6; variable, creamy to pale buff or yellowish (rarely white or greenish-grey), brown blotches in ring towards broad end and large pale and dark grey underlying; replacement clutches frequent; incubation by female, period 14–16 days; chicks fed by both parents, often shaded by female during hottest part of day, nestling period 18–20 days; fledglings dependent on adults and fed for at least 3–4 weeks after leaving nest. Breeds in first year.

Movements. Migratory. Most spend non-breeding season in sub-Saharan Africa (particularly in NE part of continent) S to S parts of Sudan and Ethiopia (rarely, S to Kenya and L Edward, near equator) and W to E Mali; winter range extends E to extreme SW Arabian Peninsula, and a few occasionally overwinter in Persian Gulf area. Passage mainly through E Mediterranean at both seasons; much more common in spring (Mar–Apr) than in autumn in e.g. Egypt, Jordan and Israel, suggesting loop migration (or difference in conspicuousness because of overflying in autumn). Autumn migration can start as early as Jun, but this mainly local post-breeding dispersal prior to main departure; leaves Balkan countries second half Aug, continuing until Sept; main migration recorded Aug–Sept, when common in Iraq, Israel, Arabia and Egypt; reaches winter quarters Aug–Nov (peak Sept–Oct). Leaves wintering grounds usually from Feb onwards, with passage through Arabian Peninsula Feb–May (peak Apr) and Egypt Mar–Apr; most birds back in breeding territories in Apr, but arrival very protracted and not reaching extreme NW of breeding range (S Bulgaria and S Macedonia) until beginning of May (exceptional record from end Feb in SW Bulgaria). On migration tends to congregate (perhaps more so than other migrating shrikes), and concentrations can occur; in Israel more than 100 occasionally recorded on peak days at favoured staging sites (five or more individuals on one bush). Defends very small (less than 0.5 ha) temporary (a few hours or days) territories at migration stopovers; in general, these held for shorter duration on spring migration than in autumn.

Status and Conservation. Not globally threatened. Uncommon and local, provisionally evaluated as declining in Europe, but to large extent insufficiently known. Densities of up to 6 pairs/1.9 ha recorded in riverine poplar plantation, Turkey, holding up to 90,000 breeding pairs, possibly has majority of world population. About 3000–4000 pairs thought to occur in some of the Balkan countries, the bulk in Bulgaria and Greece; reassessed estimation for Cyprus gives population of 4000–10,000 breeding pairs. Few data for Middle East; population in Israel in 1970s and 1980s estimated at a few thousand pairs. Possible slight increase suspected in Bulgaria (where species may have been overlooked for long time) and Macedonia. Declining in Greece and Turkey; widespread decline in Israel in 1950s and 1960s apparently due to pesticides. In non-breeding range status unknown; formerly not uncommon in Somalia, now rare. Protected in most countries, in some listed as “rare”. In Europe main probable cause of declining trends is degradation of favoured diverse habitats; during migration suffers from shooting in Turkey, Middle East and Africa. Locally subject to persecution on breeding grounds in Greece and Syria, as considered a bird of ill omen. Has recently started to occupy plantations, which have replaced natural woodland, and this adaptation may be of long-term conservation benefit to this species.

Genus CORVINELLA Lesson, 1831

28. Yellow-billed Shrike

Corvinella corvina

French: Corvinelle à bec jaune **German:** Gelbschnabelwürger **Spanish:** Alcaudón Piquigualdo
Other common names: (Western) Long-tailed Shrike(!)

Taxonomy. *Lanius corvinus* Shaw, 1809, no locality = Senegal.

Treated as congeneric with *C. melanoleuca* on basis mainly of similarities in morphology (e.g. long tail), vocal communication patterns, and social behaviour (co-operative breeding, gregariousness). Races intergrade, and intermediate individuals exist. Race *caliginosa* sometimes merged with *affinis*. Proposed race *chapini* (from Kavirondo, in Kenya) synonymized with *affinis*. Four subspecies recognized.

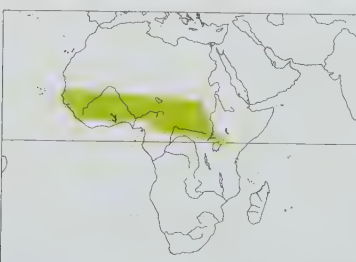

Subspecies and Distribution.

C. c. corvina (Shaw, 1809) – extreme S Mauritania, Senegal and Gambia S to Guinea-Bissau and N Guinea, E to Burkina Faso, SW Niger and NW Nigeria.

C. c. togoensis Neumann, 1900 – S part of range from W Guinea and Sierra Leone E to C & E Nigeria, N Cameroon, Central African Republic, S Chad and W & S Sudan.

C. c. caliginosa Friedmann & Bowen, 1933 – S Bahr el Ghazal (SW Sudan).

C. c. affinis Hartlaub, 1857 – S Sudan, NE DR Congo, N Uganda and W Kenya.

Descriptive notes. 30–32 cm; 58–80 g. Large shrike with very long, graduated (graduation c. 6–8.5 cm) tail and distinctive yellow bill. Male nominate race has dark brown facial mask over lores, eye and ear-coverts, broad pale buff supercilium; upperparts fawn-brown, broadly streaked black, scapulars light buff with black subterminal bar; upperwing blackish-brown, very conspicuous orange-buff patch c. 5.5 cm long at base of primaries (striking in flight), secondaries, tertiaries and greater wing-coverts with buff edges and tips; central tail dark brown with buffy tips, other rectrices become progressively paler buffy brown towards outer

tail; washed pale buffish below, narrowly streaked and barred blackish (mainly on lower throat and chest), rufous to cinnamon patch on flanks (usually concealed by closed wing); iris dark brown; bill yellow to deep yellow; legs dark green. Female is very like male, but flank patch maroon in

colour. Juvenile is similar to adult, but upperparts and underside notably barred, primary patch duller, sexes distinguishable at 11–12 weeks by colour on flanks. Races differ mainly in tone of upperparts and degree of streaking: *togoensis* is very like nominate but more heavily streaked above; *affinis* is distinctly more greyish-brown than nominate, with orange-buff primary patch smaller; *caliginosa* is very like previous, but slightly greyer and slightly more streaked. VOICE. Calls with noisy chatters, often uttered in series and simultaneously by mates (duets), or by several group-members; sometimes mimics other birds. Calls generally similar to those of *C. melanoleuca* but less sonorous; described also as reminiscent of Common Starling (*Sturnus vulgaris*). Combination of whistles, buzzes, and rasping “kzzzzkzzzz” sounds and a loud repeated “scis-scis”, “schiss-schiss” or “zrrretzrrret”; in flight “squee” notes given, sometimes terminating in chattering noise starting with “dreee-too”, “breeeu” or “ksseuu”. Most whistles quite loud, audible at up to 200 m. In breeding season repeated rapid “twee-dl-ooo” and “tlueet-tlueet” during displays; also a phrase transliterated as “may we, may we wait, may we...” or similar versions. Alarm “twe-kik...wee-tik-kik” or rasping “kzzzz-kzzzz-kzzzz”. Female beg from mate or helpers with harsh repeated notes.

Habitat. Mostly acacia (*Acacia*) savanna, but also well-wooded parks, open woodland and gardens. Breeds in dry steppe climate of Sahel; less arid areas inhabited in soudanian zone; woodland stands, e.g. *Pterocarpus lucens* in Mali, also occupied. In W Kenya, occurs at 500–1000 m in arid or semi-arid country; also at up to 2200 m in areas with more than 1000 mm rainfall.

Food and Feeding. Wide variety of insects, preferring mostly larger species such as grasshoppers and crickets (Orthoptera) and beetles (Coleoptera), but also large ants (Formicidae), termites (Isoptera), green mantids (Mantidae); spiders (Araneae), slugs, worms and caterpillars also caught. Small vertebrates such as frogs, lizards and, rarely, fledglings of passerines such as waxbills (*Uraeginthus*) occasionally eaten. Most prey caught on ground by swooping from perch or pouncing after low, short flight over a feeding area. During adverse weather, forages also on ground and by turning over litter, even pulling worms from earth in manner typical of Common Blackbird (*Turdus merula*).

Breeding. Season varies geographically; during Sahel rains from end Jun to Aug in Senegal, Jul–Oct farther S in Gambia, in most months in Ghana and Nigeria, in Jan–Feb and Apr in Kenya; locally two or three broods. Monogamous. Co-operative territorial breeder, 18 breeding groups studied in Ghana had average of 12 members (range 6–25); only one breeding pair per group, all other members are helpers (mostly progeny of breeding pair) and these defend territory, warn against predators and feed incubating or brooding female, as well as nestlings and fledglings. Nest built by breeding pair, helped by some group-members, work taking 1–4 weeks to complete, a large open cup loosely constructed from twigs, grass and sometimes leaves, lined with finer grass stems and rootlets, placed 1.5–10 m above ground (60% of nests at 3–6 m) in tree or bush and generally well concealed in foliage; in Ghana 20 tree species used (115 nests), the most frequent *Fagara zanthoxyloides* and *Bambusa vulgaris* (23% each); territory 10.5–27 ha. Clutch 2–6 eggs, usually 3–4, creamy to reddish or greenish with grey and yellowish-brown spots; replacement clutches frequent; incubation by breeding female, fed on nest by male and helpers, period 15–18 days; chicks brooded by female, fed by male and helpers (which deliver food to female), nestling period 18–20 days; young leave nest when still unable to fly, are fed by all group-members, become independent c. 45–50 days after hatching. Nests parasitized rarely (one of 160 nests) by African Cuckoo (*Cuculus gularis*) in Ghana. Breeding success relatively low, 25% in Ghana; 57% of 366 eggs hatched, most clutches lost during rainstorms and high winds, and only 44% of 159 nestlings fledged. Age of first breeding not known, but no young hatched during a six-year study had yet begun to breed.

Movements. Resident and partial migrant. All movements are on local scale, involving modest shift of range S in dry season. In S Mauritania reportedly migratory, and flocks of up to 150–200 individuals observed. S populations appear to be less migratory; a population studied for several years at Legon, in Ghana, was strictly resident, and this appears to be the case for all those inhabiting the Accra plains.

Status and Conservation. Not globally threatened. Locally common. Has a large range, with estimated global extent of occurrence of 3,500,000 km², and total population size believed to be large. Global trends not quantified, but populations appear to be stable. Reduction in use of agricultural pesticides and the conservation of semi-open habitats with dispersed traditional farming would probably be the most effective conservation measure to guarantee this species’ future.

29. Magpie Shrike

Corvinella melanoleuca

French: Corvinelle noir et blanc **German:** Elsterwürger **Spanish:** Alcaudón Pío
Other common names: (Eastern) Long-tailed Shrike(!)

Taxonomy. *Lanius melanoleucus* Jardine, 1831, Orange River, South Africa. Sometimes placed in a monotypic genus, *Orolestes*, because of distinctive plumage coloration and pattern. Treated as congeneric with *C. corvina* on basis mainly of similarities in morphology (e.g. long tail), vocal communication patterns, and social behaviour (co-operative breeding, gregariousness). Race *angolensis* sometimes synonymized with nominate, as more rarely is *expressa*. Four subspecies recognized.

Subspecies and Distribution.

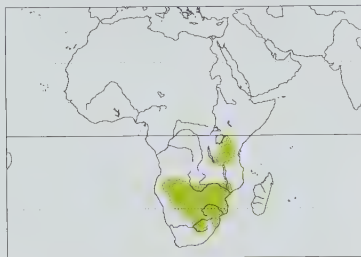

C. m. aequatorialis (Reichenow, 1887) – SW Kenya (E Masai Mara Game Park) and Tanzania (from SE L Victoria E to S slopes of Mt Kilimanjaro, S to SE L Tanganyika and SW to N L Malawi).

C. m. angolensis (Meise, 1958) – SW Angola and NE Namibia (NE of Namib Desert).

C. m. melanoleuca (Jardine, 1831) – S Zambia, Zimbabwe (except SE), Botswana (except large parts of Kalahari) and N South Africa.

C. m. expressa (Clancey, 1961) – SE Malawi, SE Zimbabwe and NW & C Mozambique S to NE South Africa (Kruger NP and NE KwaZulu-Natal) and E Swaziland.

Descriptive notes. 34.5–50 cm, including tail (male 22.5–35 cm, female 21.5–34 cm); male 55–97 g, female 71–96 g (*melanoleuca*). A large black-and-white shrike with an exceptionally long, strongly graduated tail. Male nominate race has head and mantle glossy black, extensively white scapulars and sometimes primaries and some greater upperwing-coverts white-tipped, large white patch near base of primaries (very prominent in flight); tail black; chin and throat to chest black with dark brownish gloss, belly and flanks black and less glossy, undertail-coverts black; iris brown; bill and legs black. Female is similar to male, but with large white patch on flanks, possibly even more extensive when breeding. Immature has black areas of adult replaced by dark brown without gloss, graduated tail up to same length as adult’s but dark brownish-black with buff tips (fledgling’s tail shorter), feather tips on mantle rufous-brown, scapulars whitish and tipped buff, rump buffy grey, wing-coverts and remiges with buff tips, underparts dark brown with whitish feather tips (giving barred impres-

sion), variable amount of buffy white on flanks. Races differ mainly in size: *aequatorialis* has much shorter tail (up to 26 cm), also deeper black on chin to breast, smaller white tips on secondaries and tertials; *angolensis* has shorter tail, supposedly not exceeding 28 cm; *expressa* is smaller, has shorter wing, remiges with larger white tips, rump greyish (rather than whitish). VOICE. Noisy, with large variety of sounds reflecting complex social organization. Territorial calls various loud, repeated whistles e.g. “teeloo-teeloo”, first note higher than following one, resembling “needle boom needle boom” or “come here come here”; breeding pair calls in duet, “teeloo” by male and higher-pitched “tleeu” by female. Scolding “chack” or “tchzzrrr” alarm used for ground predators, more intense and prolonged as nest-site approached; alarm call for aerial predator shorter. Begging call of breeding female repeated “tzeew”, becoming louder and more frequent as group-member approaches nest; begging call of young similar.

Habitat. Mainly savanna woodlands and open park-like savanna with scattered acacia (*Acacia*) growth and short-grazed grass or bare-ground patches; also broadleaf woodland and mopane (*Colophospermum*) habitat. At SW limit in Botswana most common in moist areas, river valleys and vleis, always with acacia trees, but also in semi-desert habitat. Found locally in town parks (South Africa) and suburbs (Zimbabwe). Mostly in lowlands; at N limit in Kenya found at up to 1800 m.

Food and Feeding. Feeds mainly on arthropods. Observed prey items ants (Formicidae), termites (Isoptera), grasshoppers (Orthoptera), mantises (Mantodea), millipedes (Diplopoda) and large grubs; also lizards, mice, fresh and rotting meat and fruit. Stomach contents consisted mainly of grasshoppers and beetles (Coleoptera). Once observed to catch and partly eat a Bronze Mannikin (*Lonchura cucullata*), but in general birds seem a very rare food source. Nestling diet insects, lizards and rodents. Scans for prey from top and outer branches of small trees and bushes, also from artificial perches such as telephone wires and fences. Usually catches prey by dropping down on to it from perch, or by grasping or plunging on item after a low flight of sometimes more than 20 m; prey occasionally caught in air. Other catching techniques are hopping around on ground to disturb prey, and gleaning items from leaves and branches. Usually forages solitarily, but group-members often attracted to food source of foraging individual; feeds gregariously on ground on ants and termites when these emerge in large numbers.

Breeding. Season largely coincides with rainy season, in S (nominate race) from Aug to Mar (Oct–Mar in Zambia, mainly Oct–Nov in Zimbabwe and N South Africa, Nov–Feb in Botswana) and Jan–Apr in E Africa (*aequatorialis*); two broods probably common. Probably monogamous. Gregarious and regularly co-operative territorial breeder, group size varying from two (breeding pair only) to eleven during breeding season (in austral winter up to 19); social organization little known, probably one breeding pair within a group, seemingly breeding female dominant; in one study group home range estimated at 23 ha and 32 ha in one area and average of 22 ha in another, in a second study 70 ha. Nest built by breeding pair, but one study suggests probably one or more helpers also involved; a compact cup made from twigs, fibres, rootlets and grass, also artificial material if available, lined with finer material but with ragged exterior, placed 1.5–12 m (average c. 4 m) above ground in thorny tree, especially acacia; breeding territory of c. 3 ha around nest. Clutch 1–6 eggs, usually 3–5, buff to yellow with brown and grey spots; replacement clutches frequent; incubation by breeding female only, fed by male and apparently also by certain other members of group, period 16–20 days; hatching usually asynchronous, chicks brooded by female, fed by parents and by at least one helper (probably more), young of first brood known to feed nestlings of second brood, nestling period 19–24 days; young start to forage for themselves in second week after fledging, but fed by adults at decreasing rate for up to 8 weeks after leaving nest. Breeding success variable: in one study a pair made seven breeding attempts, of which two successful; success per pair (at least one nestling leaving nest during breeding season) 85%, at least 2:1 fledglings per pair; fledging success per nest (at least one nestling leaving nest) 47%, fledging success per egg 31%; some nest failures caused by strong winds and possibly by human disturbance, also suspected nest predation by crows (Corvidae), monkeys and raptors.

Movements. Mainly resident. In dry season regular movements suspected near borders of range in N Namibia and C Zambia; rare (non-)breeding visitor in S Malawi. Moves temporarily into areas cleared by fires. Possible movements by individuals leaving group towards start of breeding season.

Status and Conservation. Not globally threatened. Uncommon to locally very common. Disappears or decreases in areas severely modified by man. Indications of decline in some areas, e.g. SW Kenya (only few pairs remaining in E Masai Mara Game Park). Seems generally not to adapt well to man-made habitats, but in Zimbabwe several groups have for long bred in suburbs of Bulawayo.

Bibliography. Baillie *et al.* (2004), Clancey (1964), Dean (2000), Dowsett *et al.* (2008), Fry *et al.* (2000), Grimes (1976, 2002), Hall & Moreau (1970), Harris & Arnott (1988), Harris & Franklin (2000), Hockey *et al.* (2005), Kopij (2005), Lefranc & Worfolk (1997), Lepage (2008), Lewis & Pomeroy (1989), du Plessis *et al.* (1995), Zimmermann *et al.* (1996).

Genus EUROCEPHALUS A. Smith, 1836

30. Southern White-crowned Shrike

Eurocephalus anguitimens

French: Eurocéphale à couronne blanche **Spanish:** Alcaudón Coroniblanco
German: Weißscheitelwürger
Other common names: (Smith’s) White-crowned Shrike

Taxonomy. *Eurocephalus anguitimens* A. Smith, 1836, “between Latakoo and the Tropic” = northern South Africa.

Genus formerly included with the helmet-shrikes (Prionopidae), which were at the time treated as a subfamily of Malaconotidae; recent studies, however, suggest that it belongs with Laniidae. Forms a superspecies with *E. ruppelli*. Two subspecies recognized.

Subspecies and Distribution.

E. a. anguitimens A. Smith, 1836 – SW & S Angola and N & NE Namibia E to Botswana (except SW), extreme S Zambia, C plateau of Zimbabwe, and N South Africa (W Limpopo Province).

E. a. niveus Clancey, 1965 – SE Zimbabwe and adjacent SW Mozambique S to NE South Africa (E Limpopo S to extreme N KwaZulu-Natal) and NE Swaziland.

Descriptive notes. 24 cm; 51–70 g. A large stocky shrike with relatively short tail. N nominate race has forehead, crown and nape white, black line from lores passing just through and below eye and linking with large sooty black patch over ear-coverts, rear side of throat and side of nape, often sooty brown on ear-coverts and sides of neck; upperparts, including scapulars, ashy brown; upperwing dark brown, all flight-feathers narrowly fringed and tipped pale, wing-coverts slightly less dark than remiges; tail dark brown, feathers very narrowly tipped and fringed pale when fresh; chin and throat to central belly off-white, tinged buff on upper

breast, both lower belly and lower flanks and vent ashy brown, undertail-coverts grey-brown; iris dark brown; bill black; legs dark brown. Sexes similar. Juvenile is similar to adult, but with greyer crown mottled and faintly barred, wing feathers edged and tipped buffish, underparts washed ashy brown, bill paler, legs greyish. Race *niveus* is very like nominate, but paler on mantle and scapulars. Voice. Repertoire diverse and complex. Calls generally loud, with some harsh and strident squeaks and squawks, some with nasal quality. Territorial calls probably started by dominant male with “kaekaew” (sounding like a toy trumpet), to which others respond in chorus with diversity of calls including stuttering and bleating “k-k-k-kaev”, “skwee-kwee-kwee”, “kaeeer”, and “chuk” or “chut” calls. Threat call a low “krrr”; alarm noisy, one bird uttering loud nasal “kaeeer” to which others instantly respond with repeated “keekekeke...” in chorus. Contact a bleating “kaee” and repeated “k-kaeeke...”. A stuttering “kida-kida-kida...” seems to be used in welcoming display or when approaching fledglings with food; other calls apparently when preferred food is found are “tchetchetche...”; begging call of young loud wheezy “skaa-skaa-skaa...”.

Habitat. Open woodland and open parkland. Requires rather tall deciduous thorny trees and sparse ground layer. Often found near large rivers, and in drier regions in W of range commonest in riverine bush, but appears also in semi-desert thorn savanna. Prefers dry low-lying areas; in NE South Africa absent from highveld, but widespread in bushveld and lowland regions. Sometimes found in village gardens.

Food and Feeding. Arthropods, mainly insects. Seems to favour large prey such as locusts and grasshoppers (Orthoptera), Lepidoptera (caterpillars), Hymenoptera (black bees), termites (Isoptera) and beetles (Coleoptera); feeds also on millipedes (Diplopoda) and small fruits. Scans surroundings from perch 3–6 m above ground; most prey taken on ground. Gleans items from trunks, branches and foliage; sometimes hangs upside-down to investigate likely sites; also flutters among foliage to flush prey. Aerial hawking commonly practised. Occurs singly, in pairs and in small groups; moves through woodland systematically. Size of territory of one observed group during austral winter was c. 200 ha.

Breeding. Laying from Sept to Feb, mostly Oct–Dec; appears to be single-brooded. Monogamous. Co-operative and territorial, single breeding pair occasionally assisted by helpers; degree of co-operative breeding seems to vary, sometimes solitary pair, sometimes 4–5 helpers; breeding male observed to ignore helper which solicited copulation, but occurrence of clutches twice normal size (likely result of two females laying in same nest) suggests potential extra-pair copulations and/or intra-group brood parasitism. Nest built by both pair-members, sometimes aided by one or two helpers, work taking 3–4 weeks; a very tidy, strong, perpendicular-sided cup up to c. 12.5 cm across and c. 7.5 cm high, made from fine yellow grass stems, hair and feathers occasionally used for lining, the exterior plastered with an even covering of cobweb (giving nest a smooth silvery-grey finish that matches lichen-covered branch), placed normally at height 4–6 m on lateral branch of acacia (*Acacia*), occasionally in deciduous tree (e.g. *Brachystegia*); nest may be renovated and reused. Clutch 2–6 eggs, usually 3–4, occasional larger clutches (e.g. 10 eggs) probably product of two females, whitish, with grey and brown spots and blotches mainly at larger end; incubation by breeding female, sometimes (for short stints) by helpers, period c. 20 days; nestling period reported as 18–20 days; fledglings fed by all group-members.

Movements. Local seasonal movements reported. In years of drought appears to be nomadic, with irregular irruptions.

Status and Conservation. Not globally threatened. Fairly common and quite widespread in suitable habitats; rather localised in some regions. Population seems to be stable, and habitat not under any immediate threat. Kept in captivity.

Bibliography. Dean (2000), Hall & Moreau (1970), Harris, T. (1998), Harris, T. & Arnott (1988), Harris, T. & Franklin (2000), Hockey *et al.* (2005), Lefranc & Worfolk (1997), Parker (1997b), Vicent (1949).

31. Northern White-crowned Shrike

Eurocephalus ruppelli

French: Eurocéphale de Rüppell **German:** Rüppellwürger **Spanish:** Alcaudón Culiblanco
Other common names: White-rumped Shrike

Taxonomy. *Eurocephalus ruppelli* [sic] Bonaparte, 1853, White Nile, Shoa, Ethiopia. Genus formerly included with the helmet-shrikes (Prionopidae), which were at the time treated as a subfamily of Malaconotidae; recent studies, however, suggest that it belongs with Laniidae. Forms a superspecies with *E. anguifimans*. Race *erlangeri* sometimes considered insufficiently differentiated, and species sometimes treated as monotypic. Additional proposed races are *deckeni* (described from Afgoi, in S Somalia), which is subsumed in *erlangeri*, and *fischeri* (Ndjiri, W of Kilimanjaro, in N Tanzania) and *boehmi* (Langenburg, NE of L Malawi, in S Tanzania), both synonymized with nominate. Two subspecies currently recognized.

Subspecies and Distribution.

E. r. ruppelli Bonaparte, 1853 – extreme SE Sudan, W part of S Ethiopia, Kenya (except NE) and N & C Tanzania.

E. r. erlangeri Zedlitz, 1913 – C & SE Ethiopia, NE Kenya and extreme NW, C & S Somalia.

Descriptive notes. 19–23 cm; 42–58 g. A large stocky shrike with relatively short tail. Nominant race has forehead, crown and nape white, dull black facial mask from bill base and lores through eye to ear-coverts and side of neck; upperparts brown, darker on lower back, white rump and uppertail-coverts; upperwing and tail dark brown; chin to undertail-coverts white, dull brown on flanks and underwing-coverts; iris dark brown; bill black; legs dark grey or brown. Sexes very similar. Juvenile is darker than adult, dark brown forehead to nape, blackish area below eye, wing-coverts and back feathers with pale edges and tips, white throat, grey-brown

breast with faint barring (forming narrow band), white belly, bill paler than adult's; immature similar to juvenile but head paler, with crown white. Race *erlangeri* is somewhat larger than nominate. Voice. Little information available. Has complex repertoire with noisy, harsh nasal quality, very similar to voice of *E. anguifimans* but accelerated. Calls normally short, rather high-pitched, sometimes a single squawk or squeak, or 2–3 chattering, repeated sharp “kek-kek”, “kak-kak” or “chee-cheee” notes; also longer phrases made up of fast series of notes, e.g. “chrrk”, “wirk-wirk”, “yeark-yeark”, “wuk-wuk”, or “yerk-yerk-yerk-yerk”; also a bleating “weeyer wók” call. Juveniles give sharp “skeet”.

Habitat. Dry thornbush areas and open woodland. Typical species of acacia (*Acacia*) or *Commiphora* woodlands. In Somalia occurs on the plateau, in open acacia-aloe (*Acacia-Aloe*) country near old tribal encampments or in high mimosa trees bordering dry watercourses. In Kenya found at up to 2200 m, but commonly below 1400 m, avoiding most of the rather humid areas. Near human habitations enters gardens, parklands and similar habitats.

Food and Feeding. Mainly insectivorous, but little information available. Beetles (Coleoptera), grasshoppers (Orthoptera) and butterflies (Lepidoptera) most commonly taken; removes and discards butterfly wings. Berries also recorded. Scans from from perch 3–7 m up; most prey taken on ground, where the shrike also hops after insects. Frequently takes insects in air, and gleans items from foliage. May forage in small groups.

Breeding. Very few data. Season Mar–May and Oct in Ethiopia, Aug–Dec in Sudan, Mar–Jun in Somalia, Jan–Apr/May and Nov in Kenya, and Jun–Dec in Tanzania. Monogamous. Co-operative breeding suspected; although pairs known to breed alone, a report of three individuals perched a few centimetres from another that was incubating. Juveniles apparently have dependency period of at least 3 months. No other information.

Movements. Little information available; possibly some local seasonal movements in Sudan.

Status and Conservation. Not globally threatened. Common in most of range. Has been poisoned during spraying of Red-billed Quelea (*Quelea quelea*) colonies. Occurs in several protected areas, including Awash National Park, in Ethiopia, and Buffalo Springs National Reserve and Shaba Game Reserve, in Kenya.

Takatsukasa & Yamashina (1931). *Dôbuts. Zasshi* **43**: 486 [Zosterops rotensis], 599 [Rukia longirostra].
Temminck (1820). *Man. d'Orn. Tabl. Syst.*, 2nd edition, **1**: 143 [Lanius meridionalis].
Temminck (1820). *Planches Color.*, Livr. **5**: plate 29, fig. 2 and text [Meliphaga reticulata].
Temminck (1821). *Planches Color.*, Livr. **12**: plate 72, fig. 3 and text [Sitta frontalis velata].
Temminck (1822). *Planches Color.*, Livr. **18**: plate 108, fig. 1 and text [Chalcoparia singalensis phoenicotis]; **21**: plate 126 and text [Aethopyga mystacalis].
Temminck (1824). *Planches Color.*, Livr. **49**: plate 293, fig. 3 and text [Zosterops palpebrosus].
Temminck (1825). *Planches Color.*, Livr. **56**: plate 335, fig. 2 and text [Rhabdornis mystacalis]; **58**: plate 347, fig. 3 and text [Cinnyris solaris].
Temminck (1826). *Planches Color.*, Livr. **65**: plate 388, fig. 1 and text [Arachnothera, Arachnothera chrysogenys]; **66**: plate 394, fig. 1 and text [Pardalotus striatus ornatus], plate 394, fig. 2 and text [Prionochilus percussus].
Temminck (1829). *Planches Color.*, Livr. **80**: plate 478, fig. 1 and text [Dicaeum chrysorrheum], plate 478, fig. 2 and text [Dicaeum sanguinolentum].
Temminck (1835). *Man. d'Orn. Tabl. Syst.*, 2nd edition, **3**: 286 [Sitta neumayer syriaca].
Temminck (1836). *Planches Color.*, Livr. **101**: plate 600, figs. 1–2 and text [Prionochilus thoracicus], plate 600, fig. 3 and text [Prionochilus maculatus], plate 600, fig. 4 and text [Psaltria, Psaltria exilis].
Temminck (1839). *Planches Color.*, Livr. **102** (Tab. Mèth.): 19 [Lanius senator rutilans].
Temminck & Schlegel (1845). In: Siebold, *Fauna Jap., Aves*, Part 2: 39, plate 14 [Lanius bucephalus], plate 22 (text in Part 3: 57) [Zosterops japonicus].
Temminck & Schlegel (1848). In: Siebold, *Fauna Jap., Aves*, Part 4–8: 71 [Aegithalos caudatus trivirgatus].
Tiechurst (1927). *Bull. Brit. Orn. Club* **47(5)**: 89 [Zosterops palpebrosus nilgiriensis].
Tiechurst (1939). *Ibis Ser. 14, no. 3*: 755 [Aethopyga nipalensis karenensis].
Tickell (1833). *J. Asiatic Soc. Bengal* **2**: 577 [Aethopyga siparaja seheriae], 578 [Dicaeum agile].
Townsend, J.K. (1837). *J. Acad. Nat. Sci. Philadelphia* **7**: 190 [Psaltriparus minimus].
Tristram (1879). *Ibis Ser. 4, no. 3*: 444 [Zosterops lateralis vatensis].
Tristram (1882). *Ibis Ser. 4, no. 6*: 135 [Zosterops rendovae].
Tristram (1889). *Ibis Ser. 6, no. 1*: 229 [Zosterops japonicus loochooensis], 555 [Dicaeum nitidum, Leptocoma sericea christinae].
Tristram (1894). *Ibis Ser. 6, no. 6*: 29, plate 3 [Zosterops metcalffii], 31 [Zosterops sanctaecrucis].
Tschusi & Zarudny (1905). *Orn. Jahrb.* **16(3/4)**: 140 [Sitta europaea rubiginosa].
Tweeddale (1877). *Ann. Mag. Nat. Hist. Ser. 4, no. 20*: 95 [Dicaeum trigonostigma xanthopygium], 536 [Prionochilus olivaceus], 537 [Aethopyga bella].
Tweeddale (1877). *Proc. Zool. Soc. London* **1877(3)**: 547 [Dicaeum hypoleucum mindanense, Leptocoma sperata juliae].
Tweeddale (1878). *Proc. Zool. Soc. London* **1877(4)**: 760, plate 76 [Oriolus steerii assimilis], 762 [Zosterops everetti], 762, plate 77, fig. 2 [Dicaeum quadricolor], 829 [Dicaeum trigonostigma cinereigulare], 830 [Anthreptes griseigularis]; **1878(1)**: 286 [Zosterops nigrorum]; **1878(2)**: 343 [Arachnothera longirostra flammifera]; **1878(3)**: 620 [Cinnyris jugularis aurora].
Ulfstrand (1960). *Bull. Brit. Orn. Club* **80(1)**: 12 [Anthoscopus caroli pallescens].
Unitt & Rea (1997). In: Dickerman, *The Era of Allan R. Phillips: A Festschrift*: 180 [Certhia americana phillipsi].
Valenciennes (1826). In: Levrault, *Dict. Sci. Nat.* **40**: 227 [Lanius vittatus].
Vaurie (1950). *Amer. Mus. Novit.* **1752**: 5 [Sitta cinnamoventris koelzi].
Vaurie (1955). *Amer. Mus. Novit.* **1752**: 10 [Lanius vittatus nargianus].
Verreaux, J. (1865). *Nouv. Arch. Mus. Hist. Nat. Paris (Bull.) Ser. 1, no. 1*: 78, plate 5, fig. 1 [Sitta villosa].
Verreaux, J. (1867). *Rev. Mag. Zool. Ser. 2, no. 19*: 173, plate 15 [Aethopyga gouldiae dabryii].
Verreaux, J. (1869). *Nouv. Arch. Mus. Hist. Nat. Paris (Bull.) Ser. 1, no. 5*: 36 [Aegithalos fuliginosus].
Verreaux, J. (1870). *Nouv. Arch. Mus. Hist. Nat. Paris (Bull.) Ser. 1, no. 6*: 34 [Sitta europaea sinensis], 39 [Aegithalos glaucogularis vinaceus].

SUMMARY OF VOLUME 13

REMIZIDAE (Penduline-tits)
AEGITHALIDAE (Long-tailed Tits)
SITTIDAE (Nuthatches)
TICHODROMIDAE (Wallcreeper)
CERTHIIDAE (Treecreepers)
RHABDORNITHIDAE (Rhabdornis)
NECTARINIIDAE (Sunbirds)
MELANOCHARITIDAE (Berrypeckers and Longbills)
PARAMYTHIIDAE (Painted Berrypeckers)
DICAEDIDAE (Flowerpeckers)
PARDALOTIDAE (Pardalotes)
ZOSTEROPIDAE (White-eyes)
PROMEROPIDAE (Sugarbirds)
MELIPHAGIDAE (Honeyeaters)
ORIOOLIDAE (Orioles)
LANIIDAE (Shrikes)

TECHNICAL DETAILS

- 310 x 240 mm
- 880 pages
- 60 colour plates
- 536 photographs
- 611 distribution maps
- more than 6000 bibliographical references
